5 although the population were initially 42 conventional InSAR and related time
6 evacuated they had returned to their 43 series techniques (e.g. Persistent
7 homes [4]. Displacements recorded over 44 Scatterer InSAR and small baseline
8 time could provide critical additional 45 InSAR) can identify, map and monitor
9 information for predicting the possible 46 active landslides [22-26] and even to
10 timing of impending slope failure [5]. 47 detect precursory deformation signals

11 Based on conventional in-situ survey 48 prior to their eventual failure, e.g. [27-
12 methods, the concept of ‘landslide early 49 29]. Note that spaceborne InSAR
13 warning systems’ has been proposed for 50 currently has a minimum repeat cycle of
14 several years, e.g. [6-12]. The outcomes 51 6 days for Sentinel-1, 1 day for COSMO-
15 of these works are often suggested 52 SkyMed [30], 11 days for TerraSAR-X
16 warning criteria for specific locations. 53 and longer for other satellites, which
17 Successful early warning cases, where a 54 represents a major limitation of
18 clear warning was given prior to 55 spaceborne InSAR for early warning
19 catastrophic slope failure, have been very 56 systems.

20 limited due to the inadequate temporal 57 In-situ global navigation satellite
21 and spatial precision of ground 58 system (GNSS) monitoring is capable of
22 observations [13]. Building trustworthy 59 measuring three-dimensional landslide
23 real-time early warning systems (capable 60 motion at very high temporal frequency
24 of identifying the ‘very high-risk time’ to 61 (e.g. 20 Hz) and spatial accuracy (2-4 mm
25 prompt short-term evacuation) with 62 in plan and 4-8 mm in vertical) [31].
26 suitable spatial and temporal precision is 63 Other in-situ monitoring methods include
27 an important but difficult challenge. 64 extensometers, inclinometers, and pore

28 Spaceborne Synthetic Aperture 65 water pressure sensors. However, these
29 Radar (SAR) sensors emit radar signals 66 methods only provide point-based
30 and record the amplitude of the 67 measurements at sensors that are costly to
31 backscattered signal as well as the phase 68 install and maintain. Thus in-situ
32 (from which the changes in range 69 observations are limited by the number of
33 between satellite and Earth’s surface can 70 sensors that can be deployed at the key
34 be inferred) [14]. Interferometric SAR 71 locations and may not capture the spatial
35 (InSAR) is a powerful tool for measuring 72 variations in landslide motion prior to
36 the Earth’s surface motion over large 73 failure. There are two obvious hurdles to
37 regions (e.g. [15-17]) in all weather 74 the deployment of ground-based

1 monitoring techniques: (i) the sites with 37 observation (EO) is now within our
2 potential landslides should be detected 38 grasp. We believe that this is a message
3 prior to their failure; and (ii) the key 39 that is both important and timely. It is
4 monitoring locations in the landslide 40 important because landslides kill
5 bodies should be identified. 41 thousands of people every year,

6 Spaceborne InSAR and in-situ 42 predominantly in those parts of the world
7 sensors are complementary tools to 43 that are poorest and thus least able to
8 monitor surface displacements given 44 protect themselves. It is timely because,
9 InSAR's high spatial resolution (metres 45 though early warning has long been
10 to 10s metres) over a wide region (e.g. 46 touted as a 'golden bullet' in landslide
11 250 km x 250 km for Sentinel-1) but 47 risk mitigation, it requires accurate
12 limited temporal resolution (constrained 48 predictions that have generally been out
13 by the frequency of satellite overpasses) 49 of reach until now.

14 and in-situ sensors' fine temporal 50
15 resolution at their locations. We suggest 51

16 that it is now both feasible and timely to 52
17 combine these EO technologies to build 53
18 an integrated landslide early warning 54
19 system. In this paper, the 2017 Xinmo 55
20 (Sichuan, China) landslide is used to 56
21 demonstrate the ability of spaceborne 57
22 InSAR to identify precursory landslide 58
23 deformation, while the 2017 Dangchuan 59
24 #4 landslide in Heifangtai (Gansu, China) 60

METHODOLOGY

The InSAR dataset for the time series
displacement extraction of Xinmo
landslides includes 29 descending SAR
images acquired by Sentinel-1A/1B
satellites from 09 November 2015 to 19
June 2017 SAR on every 6-24 days.
ESA's Sentinel-1A/1B satellites operate
day and night performing C-band
microwave SAR imaging, providing
radar imagery with a wide coverage (e.g.
 250×250 km) and a short repeat cycle
(6-24 days). The SAR data in this study
were interferometrically processed with
GAMMA software. Shuttle Radar
Topography Mission (SRTM) with 30 m
horizontal resolution was used to
simulate and eliminate the topographic
phase. Interferograms were filtered by
the adaptive filtering method to reduce
the noise. Coherent pixels were detected
using the full-rank matrix approach

demonstrated in [33] and their time series analysis was performed following the InSAR time series integrated atmospheric estimation model (InSAR TS+AEM) described in [34]. Both the coherent pixel detection approach and the InSAR TS+AEM method have been successfully used in previous InSAR studies. The mean velocity map and time series displacements results were finally geocoded into WGS84 coordinate system.

The Heifangtai area has been monitored with a range of in-situ sensors including

7 GNSS receivers, 34 crackmeters, 2 range gauges and 13 piezometers since 2017 by researchers from the State Key Laboratory of Geohazard Prevention and Geoenviroment Protection (SKLGP) at Chengdu University of Technology. The data collected by all the sensors was transmitted to SKLGP in real time with GPRS (General Packet Radio Service). Note that the crackmeter was a real-time adaptive one developed by SKLGP [35], which acquired one sampling per hour in normal conditions but automatically increased its samples when a displacement acceleration was detected.

RESULTS

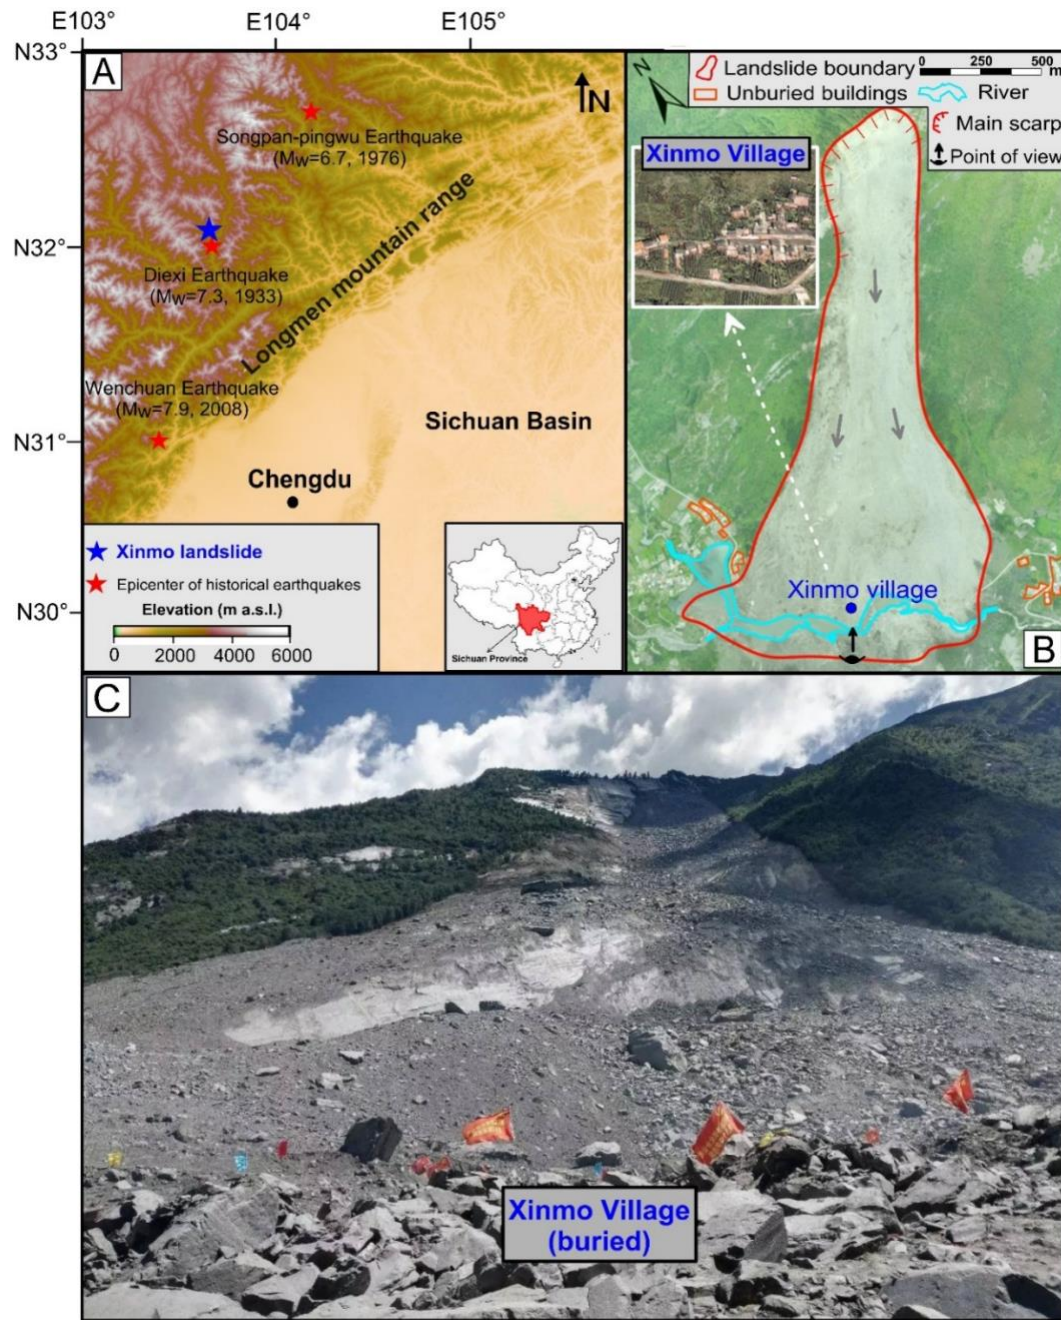

Pre-failure movement signals revealed with spaceborne InSAR

On 24 June 2017, a landslide of 13 million cubed meters suddenly buried Xinmo village, Sichuan province, China,

causing 10 deaths, with 73 persons still missing. Xinmo village is located on the left bank of the Songping River, a first-order tributary of the upper reaches of Minjiang River [36]. The surrounding steep slopes are prone to rock falls, landslides, and debris flows [37]. The region is tectonically active with several active faults nearby that have generated three $M_w \geq 6.7$ earthquakes since the 1930s (Fig. 1A). Xinmo village itself was built on the deposits of an old landslide triggered by the 1933 M_w 7.3 Diexi earthquake [36, 38] (Fig. 1A).

To explore the pre-failure displacement history of the Xinmo landslide, InSAR analysis was performed on Sentinel-1 data to determine a mean velocity map and a time series of landslide motion for a ~1.5-year period prior to failure (Fig. 2). The accumulative displacement map during the period from November 2015 to June 2017 (Fig. 2A) shows that the area near the head scarp of the landslide exhibited clearly detectable displacements with a maximum of 3 cm preceding failure. Figs 2C, 2D and 2E, show the displacement times series results for three selected points P1, P2 and P3 whose locations are shown in Fig. 2B. The last three acquisition dates are 26 May 2017, 07 June 2017 and 19 June 2017 (5 days before the failure), respectively. A dramatic acceleration can be observed during the period from 07 June 2017 to 19 June 2017 (from 17 days before the failure). It should also be noted

1 that all the interferograms were carefully 12 This clearly demonstrates that

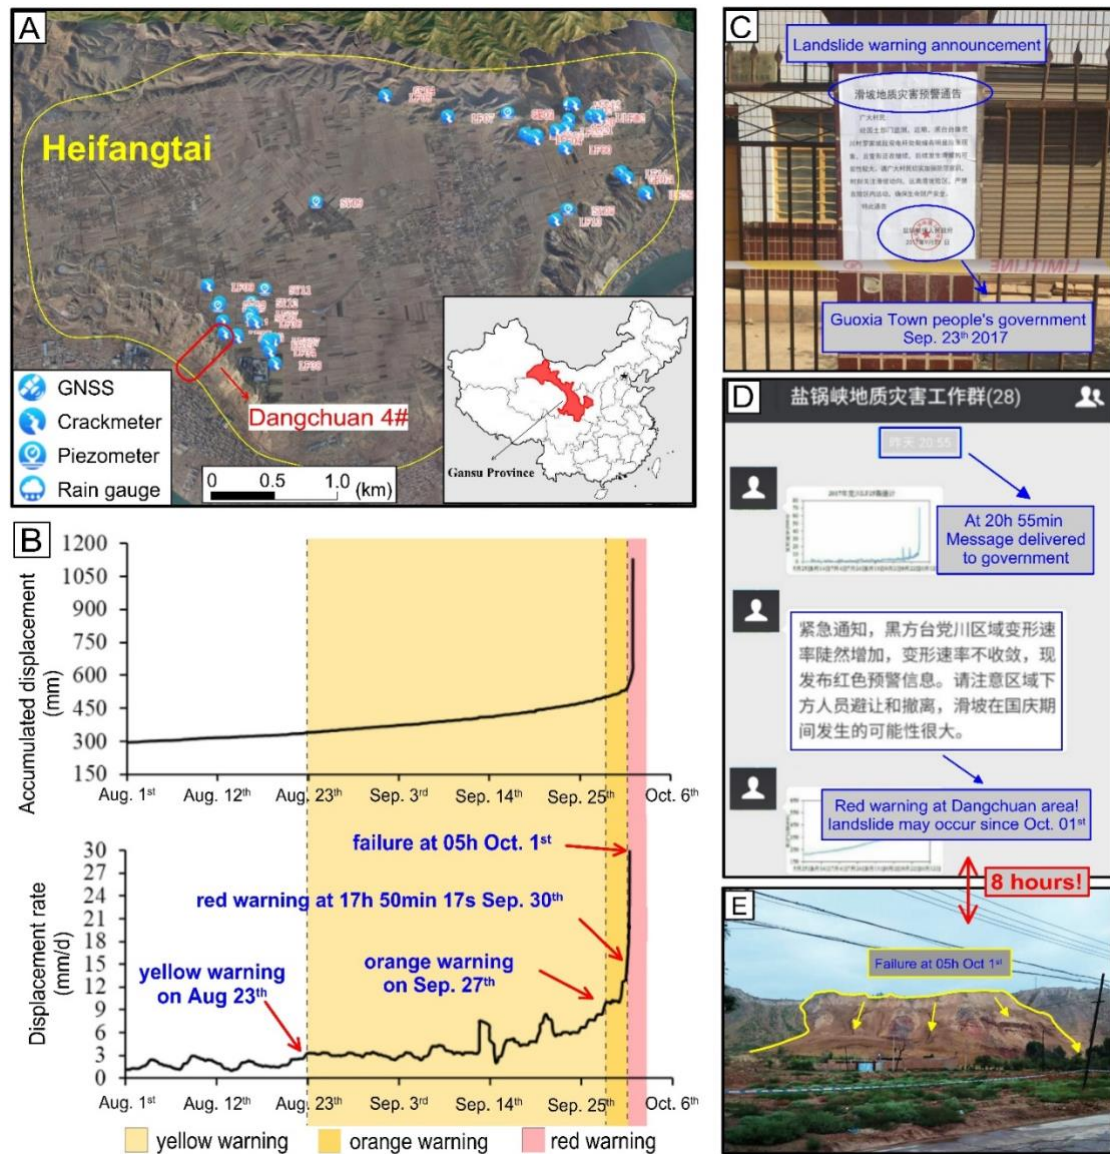

Fig. 3. landslide warning at Dangchuan 4# landslide in Heifangtai. (A) The location of Dangchuan 4# landslide with various in-situ sensors; (B) cumulative displacement and displacement rates from a crackmeter installed across the trailing head scarp edge during the period from 1 August 2017 to 1 October 2017; (C) On 23 September 2017 a photo of Heifangtai landslide warning announcement which was posted on a pillar in Guoxia town by the local government; (D) At 20:55 on 30 September 2017, a red warning message was delivered to the local government through WeChat app; (E) The post-failure photo of the Heifangtai landslide (Dangchuan 4# slope) which failed at 05:00 on 1 October 2017.

1 The crackmeter observations showed 5 was issued to the village head and local
2 a clear acceleration in the displacement 6 government by text message, informing
3 rate at Dangchuan 4# on 23 August 2017 7 them to: 'pay close attention to this slope
4 (Fig. 3B), and hence a yellow warning 8 and prepare for disaster prevention'.

9 After a detailed field investigation, the
 10 local government confirmed the warning
 11 and released an official landslide warning
 12 announcement to local communities on
 13 23 September 2017 with several alert
 14 boards posted around the landslide area
 15 (Fig. 3C). On 27 September 2017 the
 16 yellow warning was upgraded to an
 17 orange warning due to the accelerating
 18 displacement rate measured at the
 19 crackmeter. At 17:50 on 30 September
 20 2017, a red warning was released
 21 automatically by the system (Geohazard
 22 Real-time Monitoring and Early Warning
 23 System [40]) developed by SKLGP,
 24 which was confirmed by a panel of
 25 experts. Three hours later (at 20:55 on 30
 26 September 2017), an official red warning
 27 was issued to the local government (Fig.
 28 3D), prompting a government led
 29 emergency response and evacuation. The
 30 local government immediately started
 31 their emergency response, and more than
 32 20 villagers in the landslide hazard zone
 33 were evacuated. At 05:00 on 1 October
 34 2017, a landslide occurred (Fig. 3E),
 35 damaging several buildings but with no
 36 casualties thanks to the early warning
 37 [32].

38 This successful case clearly
 39 demonstrates the potential importance of
 40 real-time displacement measurements
 41 and the role that in-situ sensors could
 42 play in early warning systems. A
 43 preliminary retrospective InSAR study
 44 showed that InSAR with L-band ALOS-
 45 2 images was able to capture the

accelerated movements prior to failure,
 occurring 15 days before the landslide
 (Fig. 4).

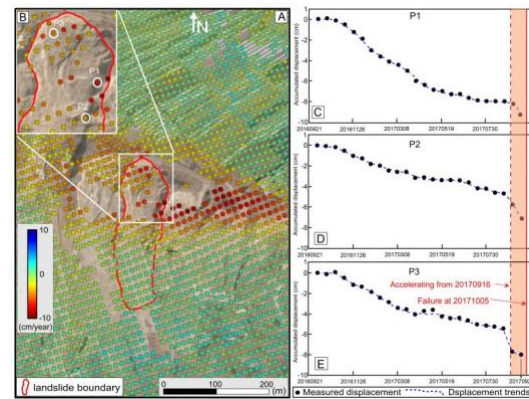

Fig. 4. Pre-event displacements of the Dangchuan 4# landslide revealed by L-band observations. (A) The mean velocity map from time series InSAR analysis. (B) Enlarged active displacement area and the location of points P1, P2 and P3; (C)(D)(E) Displacement time series for points P1, P2 and P3, respectively.

DISCUSSION

The feasibility and complementarity of EO for landslide early warning

A range of laboratory, field and theoretical studies have identified pre-failure creep acceleration of landslides and suggest that it can be divided into three phases [41-44]: (i) Primary creep, (ii) Secondary creep, and (iii) Tertiary creep (Fig.A). Primary creep is characterised by a decreasing strain rate over time, which often lasts for a short period or can be even absent in some cases [42]. Secondary creep is characterised by slow movement at near

constant rate (but with fluctuations in real slopes due to the influence of external factors, such as rainfall). The duration of the secondary creep is difficult to estimate and can last for months, years or even decades [42, 45], despite continuous displacement during this phase. Tertiary creep is characterized by a rapid acceleration of displacement until final failure [46]. Although such speed-ups may be common prior to catastrophic failure events [45], the number of actual observations of such speed-up behavior remains limited due to the absence of the right EO technologies in the right locations at the right times. Therefore, there are two primary challenges for landslide early warning: (i) monitoring surface displacements over a wide region with sufficient resolution and accuracy to identify areas undergoing secondary creep; and (ii) identifying when or under what circumstances a slow-moving landslide (i.e. in secondary creep phase) enters the accelerated displacement tertiary creep phase leading to rapid failure.

Advances in EO offer the potential to address these two challenges. In the primary and secondary phases, weekly to monthly observations would be sufficient to distinguish areas undergoing more rapid creep. In the tertiary creep phase, sub-daily sampling intervals are needed to capture the acceleration in creep (Fig. 5B). InSAR currently has a shortest repeat cycle of 1-11 days while GNSS and some other in-situ sensors can provide high-rate (e.g. 1-20 Hz) measurements. Only slow tertiary creep displacements (e.g. <0.012 m/day over a distance of 100 m for Sentinel-1 [47]) could potentially be captured by InSAR because its measuring capability is limited by the spatial displacement gradients. This limitation can be overcome by SAR pixel offset tracking (e.g. [19]) and/or Range Split Spectrum Interferometry assisted Phase Unwrapping (R-SSIAPU) method [47]; in-situ sensors generally do not have such limitations (Fig. 5C). On the other hand, InSAR offers extensive spatial coverage enabling detection of potential landslides in the primary and secondary creep phases. To monitor a single slope in its tertiary phase InSAR and in-situ sensors can provide complementary coverage in space and time.

27 and operation. There appears to be fairly 63 Earth Explorer mission, might provide a
28 widespread consensus among both 64 solution. Considerable work has been
29 academics and practitioners that EWSs 65 done to interferometrically process
30 are most effective when they are built in 66 massive SAR data sets in an automatic
31 collaboration with those at risk rather 67 way (e.g. [97]), but more should be done
32 than imposed from outside. 68 to investigate how to detect potential
33 landslides from big SAR data in a
34 consistent, reliable and smart manner.

34 **OUTLOOK**

35 The remaining three Big Questions for 71 Machine learning technologies have been
36 landslide forecasting and early warning 72 widely implemented in the field of
73 computer science and remote sensing

[98-99], where statistical techniques are employed to learn specific and complex tasks from given data. Recent studies report that machine learning has the capability to identify signals associated with geohazards from large data sets (e.g. [100]), suggesting that the integration of machine learning with EO technologies might be one encouraging solution to automatic landslide detection. To address Big Question 1, there is an urgent need to answer the following: (i) at what percentage are the detected landslides true positives? (ii) what is the percentage of the missing landslides (false negatives)? and (iii) in which scenarios are the landslides more likely be successfully detected?

Big Question 2 - when will landslides occur: A range of state-of-the-art landslide initiation and runout models have enabled us not only to estimate the location and geometry of potential landslides, but also to assess their potential impacts.

It remains a grand challenge to predict when landslides will occur. There have been a limited number of successful case studies including the 2017 Heifangtai landslide. In these cases, deformation anomalies (acceleration and/or change in pattern) observed prior to failure have been recognised as 'precursors'. However, accurate EWSs require the identification of a diagnostic signature that can be somewhat uniquely related to impending failure. The degree

to which this signature is unique, defines the confidence with which a warning can be issued, which represents a much stricter definition of 'precursor'. Further research is required to constrain the relationship between accelerated displacement and landslide failure and thus to establish these diagnostic signatures with more confidence. We suggest that widespread and long-term deformation monitoring combined with landslide observations will enable considerable progress on this problem.

Big Question 3 - how to best reduce landslide disaster risk: The experience of the cooperation between experts and local communities in Dangchuan landslide has improved our understanding of best practices for Community-Based Disaster Risk Management (CBDRM). How to best coproduce a site specific warning system with both local experts and with members of at-risk communities to reduce landslide disaster risk remains an open challenge for the whole community.

Acknowledgments - Funding: This work was supported by National Natural Science Foundation of China (NO. 41801391), the National Science Fund for Outstanding Young Scholars of China (Grant No. 41622206), the Fund for International Cooperation (NSFC-RCUK_NERC), Resilience to Earthquake-induced landslide risk in

China (Grant No. 41661134010), the open fund of State Key Laboratory of Geodesy and Earth's Dynamics (SKLGED2018-5-3-E), the Spanish Ministry of Economy and Competitiveness (MINECO), the State Agency of Research (AEI) and the European Funds for Regional Development (FEDER) under projects TEC2017-85244-C2-1-P and TIN2014-55413-C2-2-P, and the Spanish Ministry of Education, Culture and Sport under project PRX17/00439. This work was also partially supported by the UK NERC through the Centre for the Observation and Modelling of Earthquakes, Volcanoes and Tectonics (COMET, ref.: come30001) and the LICS and CEDRRIC projects (ref. NE/K010794/1 and NE/N012151/1, respectively), and by European Space Agency through the ESA-MOST DRAGON-4 project (ref. 32244). RB acknowledges support by the NASA Earth Surface and Interior focus area (ESI).

Author Contributions: Keren Dai, Zhenhong Li, Roland Bürgmann, David Milledge and Roberto Tomás contributed to the writing of the paper. Keren Dai, Zhenhong Li, Zheng Wang, Tengting Qu, Chaoying Zhao and Xiaojie Liu carried out the SAR data processing, related experiment and analysis. Qiang Xu, Xuanmei Fan and Roberto Tomás contributed to the geological analysis and result interpretation. Chaoyang He and Qiang Xu collected and analysed the crackmeter data for landslide warning in Heifangtai loess landslide. Zhenhong Li, Qiang Xu, Keren Dai, and Jianbing Peng came up with the concept of the EO-based landslide EWS proposed in this paper with contributions from David Milledge, Roland Bürgmann, Qin Zhang, Deren Li and Jingnan Liu.

Data and materials availability: All relevant data are available from the authors upon reasonable request.
