Abstract: Healthcare professionals must play an exemplary role in the field of vaccinology. It is convenient that they are trained during their time at university. The objective of this study was to determine the acceptability of the vaccines against COVID-19 in health sciences students in Spanish universities. A cross-sectional study was performed regarding the acceptance of the vaccines against COVID-19 in students in the Health Sciences Degrees in Spanish universities was performed on a sample of students of nursing, medicine, and pharmacy during the spring of 2021, via an online questionnaire with 36 questions designed ad hoc, self-administered, anonymized, and standardized. There were 1222 students participating, of Spanish nationality (97.4%), women (80.5%) and with an average age of 22.0 ± 4.8 years old. Of those, 12.3% had had the disease, 44.0% had to quarantine, 70.8% had undergone diagnostic tests, out of which 14.1% were positive. In total, 97.5% of those surveyed indicated their desire of being vaccinated, if possible, with Comirnaty[®] (74.9%). At the time of the study, 49.6% were already vaccinated. The reasons for vaccination differed according to the degree and the doubts about vaccine safety was the largest reason for reluctance. Some 37.7% suspected that there are unknown adverse effects and 85.6% of those vaccinated experienced some mild effects after injection. Vaccine acceptance and confidence in the recommendations given by health authorities is high in health sciences students.

Keywords: COVID-19; vaccine; acceptability; students; health sciences; nursing; pharmacy; medicine

1. Introduction

Vaccination has shown its efficacy as a public health tool to prevent various infectious diseases through the last two centuries, a fact which has been ratified during the current COVID-19 pandemic [1]. In this case, the vaccine deployment has been a confirmed hope to mitigate it, even though the mass vaccination strategy has been unequal and not equitable [2]. The safety of vaccines has been as much, if not more, a concern than their own

efficacy, so that the WHO and scientific societies have repeatedly affirmed that vaccines currently have an excellent safety history [3].

Having a vaccine is not equivalent to its immediate acceptance, an effect described as “Pandemic Public Health Paradox”, which associates the acceptance of a vaccine to the media impact rather than the epidemiological dynamics [4]. There are several factors that can be an obstacle to achieving acceptance of a vaccine, such as: geographic location, logistics, health system, accessibility, availability, knowledge of affordable vaccines, as well as psychological, cognitive, emotional, cultural, social factors. and politicians. The latter has recently been described in the US with vaccination for COVID-19, where counties with a high percentage of Republican voters had significantly lower vaccination rates [5,6].

Another recent study on COVID-19 vaccine uptake in 13,426 randomly selected people from 19 countries found that a transparent, evidence-based policy was needed to prevent refusal of new vaccines [7]. People who were not concerned about infection (57%; $p \leq 0.001$) had the highest rates of COVID-19 vaccine reluctance [8].

In the case of the vaccination against COVID-19, a very present threat has been caused by “infodemia”, the “disinformation” and “misinformation”, a very visible fact in this occasion, but which is not new in the history of vaccines [9–11]. At a global level, the population has been following the process of the vaccines against COVID-19, it has asked the healthcare professionals and has informed itself via the media, in a search for reassuring information which minimizes their possible doubts or rejections [12–14]. Reducing the concerns about the secondary effects of these new vaccines is achieved by providing correct and truthful information [15–17].

The determinant role of healthcare professionals in achieving higher vaccination coverage has been noted, as well as their role as a main source of information, the most influential one, for the general population [18–20]. This brings to the fore the importance of the training of the students of health sciences in the field of vaccines, not only by providing them with the specific knowledge, but also by modelling their positive attitude towards vaccination [21,22].

Healthcare professionals are the main recruiters for the vaccination process, since they use their time to advise patients, parents, families and the public about the benefits, risks, and safety of vaccines, as well as their route of administration [23–25]. They are also in charge of detecting and notifying to the health authorities the possible side effects of the vaccines [26]. The evidence shows that educational interventions are the best strategy to improve the adherence, attitude, and knowledge of the students about vaccines, since a multidisciplinary orientation of teaching contributes to going beyond the traditional approach of health education [23].

In this context, including the first line healthcare and socio-health workers as priority groups to vaccinate in the Vaccination Strategy of the National Healthcare System (SNS), was an exemplary act towards the acceptance of the vaccine by the population [27].

It is in the hands of the healthcare workers to lead the changes towards the improvement of the health of the population, and these must start from the health sciences classrooms [28]. The goal of this study was to determine the acceptance of vaccines against COVID-19 in students of university degrees in health sciences (Nursing, Medicine and Pharmacy) in various Spanish universities.

2. Materials and Methods

2.1. Design and Participants

A cross-sectional study was performed regarding the acceptance of the vaccines against COVID-19 in students in the Health Sciences Degrees in Spanish universities. The inclusion criteria were being a student of the Degrees in Nursing, Medicine, or Pharmacy in any of the participating Spanish universities. The criteria for exclusion were refusal to participate in the study or answering to the open-ended questions inappropriately.

2.2. Tool

The tool used was an online questionnaire via the Google Docs application, self-administered, anonymous and standardized, to evaluate the acceptance of the COVID-19 vaccine in students of the Degrees in Nursing, Medicine, and Pharmacy in Spanish universities. A pilot study was carried out with a group of 25 nursing students, who were not considered for this analysis. This pilot study allowed us to collect the impressions of the respondents, which were then evaluated by a group of experts to assess the understanding of the questions by the respondents and to determine the time it took them to complete the questionnaire and check the operation. internal. consistency of all the components of the questionnaire. The final questionnaire, designed ad hoc for this study, was made up of a total of 36 questions, some of which were multiple choice and others with a nominal scale. It consisted of four sections: (i) basal sociodemographic questionnaire (sex, age, origin, civil state, academic year), and personal health variables (items 1 to 15: suffering a chronic disease, use of tobacco, alcohol or psychoactive drugs); (ii) COVID-19 variables (items 11 to 16: having had COVID-19, contagion in the university environment, need for quarantine, death of some family member or friend due to COVID-19, PCR test, PCR results); (iii) acceptance of the COVID-19 vaccine (items 17 to 36: vaccination status, possibility of choice of vaccine, complete infant vaccination, previous flu vaccination, adverse effects of the vaccine, trust in the health authority recommendations, reasons for acceptance or rejection of the vaccine).

The questionnaire was designed after a literature review, with the last version approved by consensus of the team of researchers.

2.3. Procedure

The sample was composed of students who responded to the self-administered survey carried out during the months of May and June 2021. To use an appropriate sampling frame, it was decided to recruit the participants via the decanal team in their universities of origin, who provided them with information about the study, the call for participation, the informed consent, and the survey via their university email account.

Every person who showed willingness to participate and met the criteria for inclusion was included. To foment participation, the decanal team of each university sent, via email and multiple times, the details of the study, encouraging participation. The sample was by convenience on a non-probabilistic bias.

The mean \pm standard deviation was utilized for the quantitative variables, and frequency tables were used for the qualitative data. The Chi-square test was utilized to investigate the relationships between the categorical variables. The factors associated to the willingness to receive the vaccine were identified through the use a logistic regression analysis. A multivariate logistic regression was performed to identify the adverse effects associated with the type of vaccine received, with the odds ratio (OR) probability and a confidence interval (CI) of 95% calculated. The likelihood was calculated with Wald Chi-square test, and the goodness-of-fit was tested by Pearson's test. The statistical analysis was performed with the IBM SPSS Statistics for Windows, version 24.0 (SPSS Inc., Chicago, IL, USA).

2.4. Ethical Considerations

The study was approved by the Ethics Committee of the University of Alicante. Participation in the survey was anonymous and voluntary, and the questionnaire was treated completely confidentially, ensuring the privacy of the data of those surveyed. This study was conducted according to the ethical guidelines for medical research in human beings established in the Declaration of Helsinki and the EU Regulation 134 2016/679 (GDPR) relating to the treatment of personal data.

3. Results

3.1. Population Description

A total of 1222 students of health sciences subjects took part in the survey, with most of them being of Spanish nationality (97.4%), female (80.5%), living alone (67.3%) and with an average age of 22.0 ± 4.8 years. Of them, 76.5% (936) of the students were from the following universities: Catholic University of Valencia (UCV) 29.3% (359), University of Alicante (UA) 20.5% (251), Saint Anthony Catholic University of Murcia (UCAM) 17% (208) and University of Jaen (UJA) 9.6% (118).

As shown in Table 1, the participation oscillated between 37.2% and 62.1% among academic years and degrees. Most participants reported that they do not suffer any chronic disease (89.0%) and that they do not use tobacco (87.0%), alcohol (89.6%) or psychoactive drugs (98.3%). Among the university students, those studying nursing reported higher percentage of tobacco use ($p = 0.045$) and higher presence of chronic diseases ($p = 0.015$). There were no significant differences regarding the consumption of alcohol ($p = 0.07$) or psychoactive drugs ($p = 0.767$) among degrees.

3.2. Variables Relating to the COVID-19 Disease

Of the participating students, 12.3% (n = 150) had had COVID-19, most of which (81.3%) claim that they were not infected at the university. 44.3% (n = 534) had to be quarantined due to close contact with some case and 16.6% (n = 203) reported the death of some family member or friend due to COVID-19. There were no significant differences between the degrees for these variables.

Most of the students had to have some diagnostics test performed on them: PCR or antigen test (70.8%). The degrees of Nursing and Medicine were those with a higher percentage of students having taken PCR or antigen tests ($p < 0.001$). In any case, the vast majority tested negative (Table 2).

p-value = calculated for the Chi-square test group.

3.3. Variables Relating to the Acceptance of Vaccines in General and against COVID-19

As shown in Table 3, most of the students of all three degrees would vaccinate against COVID-19 and, out of these, 58.5% believe that there should be a choice of which vaccine to have, with the Comirnaty[®] vaccine being the most frequently cited option. At the time of the survey, half the students had already received the vaccine, with Comirnaty[®] being the most administered among nursing and medicine students (91.9%), while among those studying pharmacy it was Vaxzevria[®] (91.7%). In Spain you cannot choose the type of vaccine, they are recommendations from health institutions by risk group and availability of vaccines at that time (27).

Have you ever had a flu vaccination? (n = 1222)						
Yes	460 (64.2)	50 (40.3)	221 (57.9)	731 (59.8)	(56.2–63.3)	<0.001
No	256 (35.8)	74 (59.7)	161 (42.1)	491 (40.2)	(35.8–44.5)	

p-value = calculated for the Chi-square test group. * vaccinated sample.

Regarding acceptance of vaccines in general, 97.5% of those surveyed claimed having a complete childhood vaccination schedule, even though only 59.8% claimed to have ever had a flu vaccination. We found significant differences among the different health degrees. The pharmacy students reported a smaller percentage having a complete childhood vaccination schedule, as well as a lower acceptance of the flu vaccine compared to the nursing or medicine students ($p < 0.001$).

3.4. Justified Reasons for the Acceptance or Rejection of the Vaccines against COVID-19

The reasons for the acceptance or rejection towards the COVID-19 vaccine are shown in Figures 1 and 2. The reasons for the acceptance of the vaccines are associated with an attitude of individual and community protection from the disease. The most frequently cited reasons by the majority of the students were 1. Protection of others and myself. 2. The benefits of vaccines. 3. Going back to normality and obtaining the immunization passport. 4. Work-related reasons, face-to-face placements, and on the recommendation of the authorities.

The pharmacy degree showed a lower proportion of students who preferred these reasons with respect to the degrees in nursing or medicine ($p < 0.001$). Among the degrees, it is worth highlighting that the main reason for acceptance of the vaccine in the pharmacy degree was the normality/passport, whereas it was the least determinant reason for the nursing and medicine students.

The work-related reasons or the obligation to be vaccinated to carry out the clinical placements of the degree or the health recommendation were the reasons that had the least incidence towards acceptance of the vaccine among the health students, particularly among the pharmacy students.

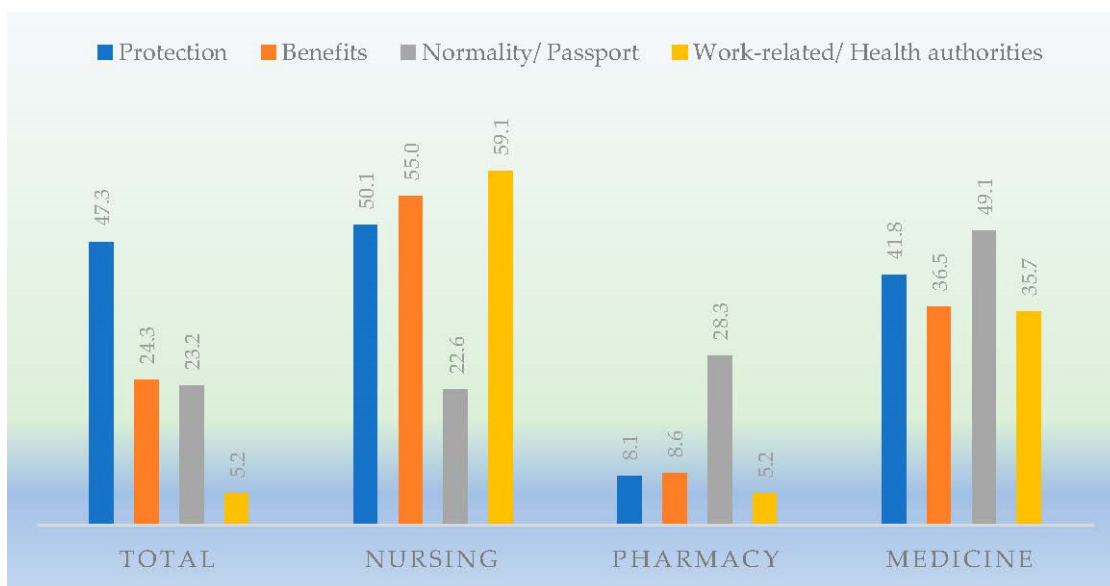

Figure 1. Reasons for the acceptance towards the vaccines against the COVID-19 disease in students of the three degrees.

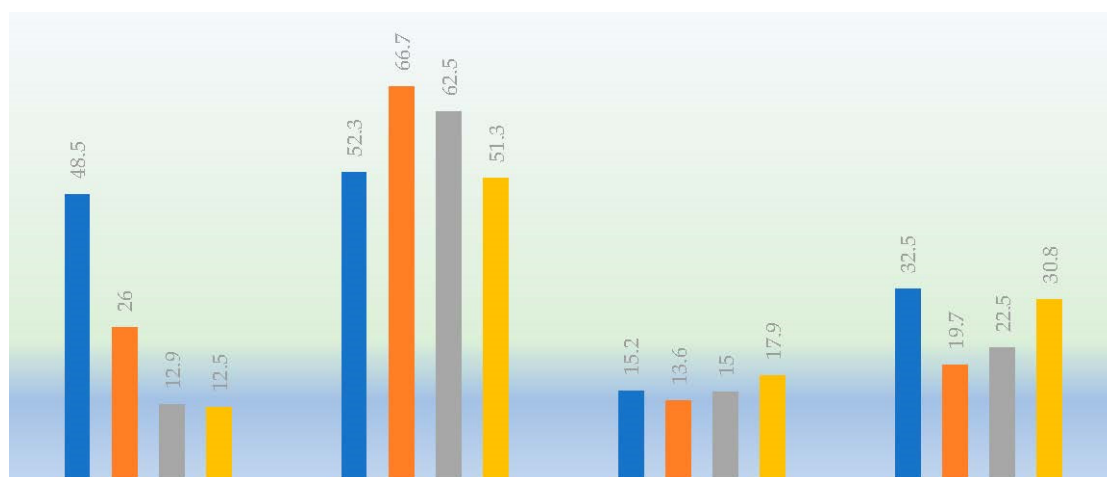

Figure 2. Reasons for the rejection towards the vaccines against the COVID-19 disease in students of the three degrees.

In Figure 2, we can see the reasons for the rejection towards the vaccines against COVID-19. The doubts about vaccine safety or the lack of knowledge about the disease were the most cited reasons.

However, and even though it was cited less often, none of the three collectives considered themselves groups at risk, and they did not even see this vaccine as necessary, despite being future healthcare workers.

3.5. Variables Relating to the Secondary Effects of the Vaccines against COVID-19

Even though most students do not believe that the COVID-19 vaccine has effects more serious than the rest of vaccines in the vaccination schedule, 37.7% (n = 461) of the participants in the study believe that the approved vaccines against COVID-19 have unknown side effects. The students in the pharmacy degree are those who cite these effects the most (p = 0.026) (Table 4).

Table 4. Beliefs and occurrence of adverse effects after the administration of the COVID-19 vaccine. (n = 1222).

p-value = calculated for the Chi-square test group. * Number of vaccinated grouped by degrees.

Most students trust the vaccination recommendations against COVID-19 made by the health authorities (89.2%); however, the number of pharmacy students who trust them is lower (82.1%) than among the nursing students (91.2%) or medicine (87.7%) ($p = 0.035$). In total, 10.4% acknowledged a lack of confidence.

When asked about the adverse effects after vaccination, most of those surveyed reported having suffered adverse effects (85.6%), without significant differences among the health degrees. The most prevalent adverse effects were pain at the injection site and tiredness. The pharmacy students showed significantly higher occurrence of fever ($p = 0.018$) and shivering ($p = 0.031$).

3.6. Multivariate Logistic Regression between the Administered Vaccines and the Declared Adverse Effects

Table 5 shows the proportion of health students who suffered the certain adverse effects surveyed in relation to the type of vaccine administered.

Receiving the Vaxzevria[®] vaccine revealed a higher percentage of appearance of all evaluated adverse effects with respect to the administration of Comirnaty[®] or Spikevax[®], except for the occurrence of pain at the injection site and swollen glands, which showed no differences among the three administered vaccines. The multivariate logistic regression analysis confirms that the type of vaccine administered is an influential factor in the occurrence of certain adverse effects. Thus, when comparing with Comirnaty[®], the administration of the Vaxzevria[®] vaccine was associated with a higher number of cases of fever (OR = 0.18, $p < 0.001$), shivering (OR = 0.58, $p = 0.044$), and vomiting (OR = 0.09, $p = 0.003$). When compared with Spikevax[®], the administration of the Vaxzevria[®] vaccine

was associated with a higher number of cases of fever (OR = 0.27, $p < 0.001$) and shivering (OR = 0.29, $p = 0.003$), but lower pain at the injection site (OR = 2.4, $p = 0.026$).

Table 5. Proportion of the occurrence of adverse effects depending on the type of COVID-19 vaccine received and multivariate logistic regression analysis.

	Total 519 (100)	Vaxzevria® 229 (44.1)	Comirnaty® 221 (42.6)	Spikevax® 69 (13.3)	Chi ²	Vaxzevria® vs. Comirnaty® OR (95% CI)	<i>p</i> -Value	Vaxzevria® vs. Spikevax® OR (95% CI)	<i>p</i> -Value

4. Discussion

This study has been able to identify the degree of acceptance of the vaccines against COVID-19 in Spanish health sciences students, who have indicated a very high intention to be vaccinated (97.5%), a result higher than other previous studies in students in USA (52.5%), France (58.0%) or China (78.9%) [29–31].

This collective is of special relevance since during their careers they will play a role of vaccination assessment and recommendation to the population, as reflected by various studies [32–45].

This research was carried out during the spring of 2021, a period between the fourth and the fifth pandemic waves in Spain, with the students completing their clinical placements in hospitals or healthcare facilities and almost half of them already being vaccinated (49.6%), especially those studying nursing (60.5%). Since the beginning of the pandemic, almost half of the students had been quarantined due to close contact or infection. Moreover, they had undergone diagnostic tests, especially in the disciplines of nursing and medicine. Those who had experienced the disease (12.3%) did not refer to the university as their location of infection.

The surveyed students trust in vaccines as a preventive method and consider it important to have a complete vaccination schedule. However, only slightly more than half reported having been vaccinated at any point against the flu, with the pharmacy students being those who had been vaccinated significantly less, a result like those of other studies [39,46].

The main reason towards acceptance of vaccination was found to be the protective effect that vaccines have on the community and themselves [47], followed by the known benefits of vaccinations and the need to return to a state of normality. Pharmacy students highlighted obtaining the COVID passport and work reasons as reasons; however, nursing and medical students who had closer contact with the disease due to their care work, indicated protection as the main reason. The acceptability of the vaccine was high in all three disciplines, even though it was higher among the medicine students, followed by those of nursing [48]. In 2021, Nguyen [49] highlighted the necessity for vaccination against COVID in healthcare staff, so it is striking that most of the surveyed students do not consider themselves a group at risk, as future healthcare workers.

Vaccine hesitancy is expressed in relation to the safety and efficacy of the vaccines against COVID-19 and the lack of knowledge about the disease itself, which agrees with previous studies [24,30,39]. Over a quarter of the students believe that these new vaccines can have unknown adverse effects, a common reason when new vaccines are added to the vaccination schedule and observed among healthcare professionals [41]. Other factors contributing to vaccine hesitancy include concerns about the secondary effects and lack of trust in the information received from public health experts [29].

The proportion of adverse effects depending on the type of COVID-19 vaccine received confirms that the administered vaccine is an influential factor in the occurrence of certain adverse effects. Most students believed that it should be possible to choose which vaccine to have administered, with the favorite one being Comirnaty®. The type of vaccine administered is an influential factor in the occurrence of certain adverse effects, as can be appreciated when comparing those from the Comirnaty® vaccine with the Vaxzevria® vaccine, with there there is statistically significantly more fever, shivering, and vomiting associated to the latter one. When Spikevax® was compared with Vaxzevria®, this one also caused a higher number of cases of fever and shivering, but less pain at the injection site. In general, all adverse effects were of a mild nature (pain at injection site, muscular pain, tiredness, or fever).

Regarding the healthcare authority issued recommendations, those surveyed manifested a good acceptance, although this statement can be improved, since 10.4% would not accept these recommendations. Despite this, this study shows better results than that of Mascarenhas AK et al. [50], where only 65.6% of the odontology students trusted the recommendations issued by the public health experts. The professionals who showed more confidence in the information provided by the health authorities are those who are more likely to vaccinate, as informed by the work by Kelekar AK et al. [42].

Even though the vaccines against COVID-19 are new, and can thus generate greater concern, the morbidity and mortality results observed during the pandemic may encourage professionals to get vaccinated despite their concerns [44]. Recently, the necessity of paying special attention to the inclusion in the study plans of topics which explain vaccines in all their processes has been highlighted [30,40,41], a view we fully share.

The main practical implication of this study is the verification of the need to train future health professionals on the potential benefits of an adequate vaccination of citizens. Therefore, the specific contents on vaccines that must be included in the training of future health professionals must be related to vaccine safety and its composition, in addition to continuous training during their professional activity due to the constant changes that require updating and recycling. Higher levels of confidence were positively related to the intention to accept vaccination. Confidence in governments improves the level of acceptance of the recommendations given [51].

The main limitations of our study were that a validated questionnaire was not found, which is not available in the scientific literature because COVID-19 is an emerging disease and the number of participants in the three degrees is not similar. However, the large sample obtained from professionals who will be the main advisors on vaccination of the population is an important strength.

5. Conclusions

The SARS-CoV-2 pandemic has highlighted the importance of vaccination and the role of healthcare professionals in their implementation. Health sciences students represent the future in maintaining a high level of vaccine acceptance. They will be seen by the population as the most reliable source of information. The high level of confidence that students show for the recommendations given by the health authorities is also a positive predictor. Therefore, the results of this study are encouraging, and support the promotion of active teaching of vaccines during the training period and further exploration of research in this area.

All authors have read and agreed to the published version of the manuscript.

Funding: This research received no external funding.

Institutional Review Board Statement: The study was conducted according to the guidelines of the Declaration of Helsinki and approved by the Institutional Review Board (or Ethics Committee) of University of Alicante.

Informed Consent Statement: Informed consent was obtained from all subjects involved in the study.

Acknowledgments: We thank the participating universities for their collaboration in disseminating the questionnaire among nursing, medicine, and pharmacy students. We also thank the students for their answers to the questionnaire that have allowed us to carry out the study.

Conflicts of Interest: The authors declare no conflict of interest.
