Two new species of *Enclisis* Townes, 1970, from Spain and Balkan Region are described and illustrated: *E. castellana* sp.n. and *E. balcanica* sp.n. Females of the new species are distinguished between, and from the closest species *E. ornaticeps*, by microsculpture of first lateral area of propodeum and mesopleurum, head features and body colour. Male of *E. balcanica* is distinguished from the closest species *E. infernator* and *E. schwarzi* by its head, less transversal, and for a longer second metasomal tergite. Male of *E. castellana* is separated from *E. ruficeps* by its microsculpture on mesopleurum and mesonotum, always on shiny background, and for the position of subdiscoideus, which reach the postnervulus in the middle or above the centre. Furthermore, data on phenology of *E. castellana* and a new illustrated key for the *Enclisis* species, excluding *E. nigricoxis* and *E. ruficoxis*, is provided. The species *E. alpicola*, *E. ornaticeps* and *E. macilenta* are recorded for the first time for Bulgarian fauna. *E. infernator* is first record for Bulgaria and Spain.

This research was supported partially by the Projects 040/2002 from Ministerio de Medio Ambiente of Spanish Government and GV06/271 from Conselleria d'Empresa, Universitat i Ciència of Generalitat Valenciana.
