**ABSTRACT:** Two efficient protocols are described for the transformation of a key chiral homoallylic sulfinamine intermediate in four steps into enantioenriched 7-methoxycryptopleurine. While one of the protocols relied on a rhodium catalyzed linear hydroformylation process, the alternative approach was based on a ring-closing metathesis from the corresponding N-allyl-sulfinamine. The cytotoxic evaluation of both enantiomers of the target compound demonstrated that the (R)-compound is much more potent than its antipode against the four cancer cell lines examined.
Phenanthroizidine alkaloids exhibit a polyoxygenated phenanthrene ring fused to an indolizidine or to a quinolizidine system (Figure 1). Importantly, while the indolizidine moiety prefers a cis-fused conformation, trans-fused quinolizidines are preferred. The stereochemistry of the pyramidal nitrogen at the ring junction may accounts for some important differences between the bioactivities of these subfamilies of alkaloids.

![Figure 1. Representative natural phenanthroizidine alkaloids.](image)

Cryptopleurine and Cryptopleuridine were the only two natural phenanthroquinolizidines known until 2002. Despite their lower natural occurrence compared to the indolizidine subfamily, phenanthroquinolizidines also exhibit very interesting bioactivities. This issue can be exemplified by Boehmeriasin A, which was identified in 2003 and exhibited IC\textsubscript{50} in the low nanomolar range against twelve cancer cell lines. Other structure-activity relationships (SAR) studies have also revealed that phenanthroquinolizidines are more potent anti-tumor agents than phenanthroindolizidine alkaloids. Encouraged by the discovery of natural phenanthroquinolizidines with important biological properties, some elegant asymmetric syntheses have been recently reported for these compounds.
It is reported that racemic 7-methoxycryptopleurine\textsuperscript{12} displays potent anti-inflammatory activity,\textsuperscript{13} as well as remarkable cytotoxicity at submicromolar concentrations against different human cancer cell lines.\textsuperscript{3a,14} In addition, the group of Wang has found that both enantiomers of the title compound show significant antiviral activity (\textit{in vitro} and \textit{in vivo}) against tobacco mosaic virus (TMV), being the \textit{R}-enantiomer the most active one.\textsuperscript{15} Moreover, the same group has recently reported that different salts of the title compound, or derivatives where the methyl groups were removed, gave excellent anti TMV activity.\textsuperscript{16} To our best knowledge, the only enantioselective synthesis reported for this promising bioactive compound takes place with partial racemization over a Parham-type cycloacylation.\textsuperscript{17}

Prompted by the unique biological activities of 7-methoxycryptopleurine and the lack of efficient protocols for its preparation with high enantiomeric purity, we report herein two alternative protocols for the synthesis of enantioenriched (\textit{R})- and (\textit{S})-7-methoxycryptopleurine. Both synthetic strategies relied on a late Pictet-Spengler formation of ring D\textsuperscript{18} and the formation of ring E was examined using either hydroformylation or ring-closing metathesis (RCM)\textsuperscript{19} as the key steps, from the same chiral homoallylic sulfonamine intermediate\textsuperscript{20} (Scheme 1). Since we have previously shown that these chiral intermediates can be efficiently transformed into phenanthroindolizidines,\textsuperscript{21} this work illustrates the versatility of these building blocks in the synthesis of both subfamilies of phenanthroizidine alkaloids.\textsuperscript{22}

\textbf{Scheme 1.} Divergent synthesis of two subfamilies of phenanthroizidine alkaloids.
Our first strategy to build ring E of (R)-7-methoxycryptopleurine is based on a linear hydroformylation of the corresponding homoallylic amine intermediate. This approach has been widely used for a range of aminoalkenes in order to provide terminal aldehydes, which upon cyclization give enamine intermediates that can be transformed into different aza-heterocycles. In this regard, we were particularly attracted by a rhodium catalyzed procedure where the syngas (CO/H₂) is conveniently substituted by formaldehyde, with excellent linear selectivity. To minimize functional group manipulations and reduce the number of steps, we first tried the direct hydroformylation of sulfimine 1, which can be prepared in six steps from commercially available starting materials (Scheme 2). However, compound 1 proved to be unreactive under different conditions reported in the literature for the rhodium(I) catalyzed hydroformylation with formalin (37% aq. formaldehyde) or paraformaldehyde. We thus prepared the N-Boc protected homoallylic amine 2, which was submitted to rhodium(I) catalyzed hydroformylation with formalin, using two different phosphane ligands (BIBHEP and Ni-Xantphos). Under these conditions, the formation of the corresponding terminal aldehyde was followed by in-situ cyclization to furnish the protected enamine 3 in moderate yield (Scheme 2). Subsequent hydrogenation of the enamine moiety followed by acidic cleavage of the Boc group took place efficiently to obtain piperidine 4. Finally, the Pictet-Spengler cyclomethylenation of this precursor was accomplished under standard conditions (formalin, HCl, EtOH, 90 °C) to obtain the target (R)-7-methoxycryptopleurine in good yield. The spectroscopic data obtained for compound 5 perfectly match with data previously reported for racemic 7-methoxycryptopleurine and the chiral HPLC analysis of this compound shows that racemization did not take place over the synthetic sequence (96:4 er, see SI). It is worth...
noting that the absolute configuration of compound 5 was confirmed to be 14a-R by comparison of the specific rotation value obtained for our synthetic sample \([\alpha]_D^{20} -81 (c 1.0, \text{CHCl}_3)\) with the one reported in the literature\(^{17}\) \([\alpha]_D^{20} -74.8 (c 0.5, \text{CHCl}_3)\).  

**Scheme 2**: Synthesis of (R)-7-Methoxycryptopleurine using Hydroformylation

Despite the good results obtained in the synthesis of compound (R)-5 [32% yield over four purification steps from compound 1 to obtain (R)-5 in 96:4 er], we were particularly interested in keeping the sulfinyl as protecting group throughout the synthetic sequence. With this strategy we anticipated a concomitant nitrogen deprotection and Pictet Spengler annulation in the final step. More importantly, we expected that keeping the chiral auxiliary until the last step would offer more opportunities to improve the enantiomeric purity of compound 5 by separation of diastereomeric intermediates. To carry forward this approach (Scheme 3) we first performed the N-allylation of compound 6,\(^{25}\) followed by ring-closing metathesis (RCM). At the outset it was not clear if the sulfinyl group would compete with the alkene moiety by the ruthenium carbene complex, preventing the desired cyclization.\(^{26}\) Remarkably, after only one hour at room temperature, the use of commercially available second-generation Grubbs catalyst allowed the RCM reaction to proceed with almost
quantitative yield. Catalytic hydrogenation of intermediate 8a was accomplished by using Adams’s catalyst to give compound 9a, followed by acidic removal of the sulfinyl group and Pictet Spengler annulation. Phenanthroquinolizidine (S)-10 was obtained in 68% yield over four purification steps from compound 6. The same synthetic sequence was applied to obtain (R)-10 from ent-6 with similar efficiency in terms of isolated yields, and neither racemization nor significant enantioenrichment was observed by chiral HPLC analysis of the products (see SI). Having developed this protocol, we thus carried out the synthesis of target compound (S)-5 from compound ent-1. Importantly, this synthetic protocol allowed the preparation of (S)-7-methoxycryptopleurine as a single isomer (>99:1 er by HPLC analysis), in 46% yield over four purification steps. The enantioenrichment of the target compound was simply achieved after conventional flash chromatography purifications of diastereomeric 8b and 9b intermediates, according to chiral HPLC analysis (see SI).

The cytotoxic activities of synthesized (R)- and (S)-7-methoxycryptopleurine were tested against four human cancer cell lines, using the MTT (3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide) method and CDDP [cis-diaminedichloroplatinum (II)] as positive control. The IC₅₀ values were determined from the corresponding inhibition/concentration curves (see SI) and the results are shown in Table 1. In all the cell lines evaluated the compound with the (R)-configuration (as natural analogues) was much more potent (IC₅₀ from 0.027 to 0.13 µM) than its (S)-enantiomer (IC₅₀ from 0.97 to 76 µM), confirming the importance of this configuration in their cytotoxicity. The cytotoxicity obtained for compound (R)-5 against human lung cancer cell lines (NCI-H460) was similar to the one previously reported³ for a racemic sample. However, for human breast cancer cell lines (MCF-7), compound (R)-5 showed a significant higher potency than it is reported for a racemic sample. A profound cytotoxicity was also exhibited by compound (R)-5 against human leukemia cells (HL-60); and most significantly against drug resistant human ovarian adenocarcinoma (NCI-ADR-RES), where paclitaxel—a potent anticancer agent—¹¹ is inactive.

In conclusion, we have developed two alternative procedures that allow the enantioselective preparation of 7-methoxycryptopleurine (5) in four purification steps from the same chiral homoallylic sulfinamine. The synthetic approach that make use of linear hydroformylation for the construction of ring E afforded the target compound in good overall yield (32%) and enantiomeric purity (96:4 er). However, better results were obtained using the ring-closing metathesis of the $N$-allyl-sulfinamine intermediate (46% overall yield in $>99:1$ er). The cytotoxicity of each enantiomer of compound 5 was evaluated against four cancer cell lines, including a drug-resistant cancer cell line, obtaining more prominent activities for the ($R$)-antipode ($IC_{50}$ up to 27 nM). To the best of our knowledge, the two procedures developed herein allow the preparation of the target compound with the highest enantiomeric purity reported to date. The cytotoxicities obtained for compound ($R$)-5 clearly support this candidate as a promising anticancer agent.

**EXPERIMENTAL SECTION**

**General Remarks.** TLC was performed on silica gel 60 F$_{254}$, using aluminum plates and visualized by exposure to ultraviolet light or with phosphomolybdic acid (PMA) stain. Flash chromatography was carried out on handpacked columns of silica gel 60 (230 – 400 mesh). Melting points are uncorrected. Optical rotations were measured using a polarimeter with a thermally jacketted 5 cm cell at approximately 20 ºC and concentrations (c) are given in g/100 mL. Infrared analysis was performed with a spectrophotometer equipped with an ATR component; wavenumbers are given in cm$^{-1}$. HRMS analyses were carried out using the Electron Impact (EI) mode at 70 eV or by Q-
TOF using Electro Spray Ionization (ESI) mode. HPLC analyses were performed using an achiral Tracer Excel 120 column for the determination of diastereomeric ratios and a Chiralcel AD-H column for enantiomeric ratios. \(^1\)H NMR spectra were recorded at 300 or 400 MHz for \(^1\)H NMR and 75 or 100 MHz for \(^13\)C NMR, using CDCl\(_3\) as the solvent and TMS as an internal Standard (0.00 ppm). The data is being reported as (s = singlet, d = doublet, t = triplet, m = multiplet or unresolved, br s = broad signal, coupling constant(s) in Hz, integration). \(^13\)C NMR spectra were recorded with \(^1\)H-decoupling at 100 MHz and referenced to CDCl\(_3\) at 77.16 ppm. DEPT-135 experiments were performed to assign CH, CH\(_2\) and CH\(_3\).

To a solution of compound 1\(^{21}\) (596 mg, 1.23 mmol, 95:5 dr) in MeOH (15 mL) was added a solution of 4M HCl in dioxane (1.2 mL, 5.00 mmol) at 0 °C. The cooling bath was removed and the reaction mixture was stirred 1.5 h at 25 °C, before being concentrated to dryness. The resulting free amine was dissolved in CH\(_2\)Cl\(_2\) (12 mL) and after cooled down the solution to 0 °C, a solution of 2 M NaOH (12 mL) and Boc\(_2\)O (304 mg, 1.40 mmol) were sequentially added. The mixture was stirred under argon atmosphere at 25°C during 2.5 h. The mixture was extracted with CH\(_2\)Cl\(_2\) (5 x 10 mL) and the collected organic layers were washed with brine (5 mL), dried over MgSO\(_4\) and concentrated to dryness. (R)-2-((2,3,6,7-Tetramethoxyphenanthren-9-yl)methyl)piperidine (4). A dry flask was charged with compound 3 (168 mg, 0.34 mmol), Pd(OH)₂ (20 % Pd on carbon powder with ca 60 % moisture, 98 mg, 0.09 mmol) and methanol (10 mL). A ballon of hydrogen gas was fitted to the equipment, and the flask was opened to vacuum for a few seconds, and then switched to the hydrogen ballon; this manipulation was repeated three times. The reaction mixture was allowed to stir at room temperature for 6 h. It was then filtered through Celite, washing with EtOAc (3 x 15 mL), and the organic solution was concentrated to dryness under reduced pressure. To the obtained residue were added methanol (3.0 mL), trifluoroacetic acid (3.0 mL, 28.00 mmol) and CH₂Cl₂ (3 mL) and the reaction mixture was stirred under argon at room temperature for 24 h. After the mixture was concentrated to dryness, a solution 2 M of NaOH (5 mL, 10 mmol) and CH₂Cl₂ (10 mL) were added to the same flask. The aqueous phase was extracted with CH₂Cl₂ (3 x 10 mL) and washed with brine (5 mL), dried over Na₂SO₄, and concentrated. (1S,R5)-N- Allyl-N-(tert- butylsulfinyl)-1-allyl-2-[phenanthren-9-yl]- ethylamine (7a). 

To a solution of sulfinamine $6^{25}$ (319 mg, 0.87 mmol) in dry THF (3 mL) under argon atmosphere at 0 °C was added a solution of KHMDS in THF (0.8 M, 1.6 mL, 1.31 mmol) via syringe. After stirring for 5 min, allylbromide (150 µL, 1.74 mmol) was added to the solution and the reaction mixture was allowed to react for 1 h at 0 °C. After this time, a solution of KHMDS in THF (0.8 M, 0.8 mL, 0.65 mmol) was added again and the reaction mixture was led to react for 1 h more at 0 °C. After complete conversion of starting material (TLC in 8:2 hexane/EtOAc), the reaction was quenched by adding a saturated aqueous solution of NH$_4$Cl (5 mL) and the aqueous phase was extracted with EtOAc (3 x 10 mL). The collected organic layers were washed with brine (2 x 5 mL), dried over MgSO$_4$ and concentrated under reduced pressure.
