Just Accepted

"Just Accepted" manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.
Diastereoselective [3+2] vs [4+2] Cycloadditions of Nitroprolinates with α,β-Unsaturated Aldehydes and Electrophilic Alkenes: An Example of Total Periselectivity

ABSTRACT: Diastereoselective multicomponent reaction of enantioenriched 4-nitroprolinates, obtained by enantioselective 1,3-dipolar cycloaddition (1,3-DC) of imino esters and nitroalkenes, with α,β-unsaturated aldehydes and electrophilic alkenes proceed with total periselectivity depending on the structure of the aldehyde employed. This process evolves through a [3+2] 1,3-DC when cinnamaldehyde is used in the presence of an azomethine ylide giving the corresponding highly substituted pyrrolizidines with endo-selectivity. However, in the case of the α,β-unsaturated aldehyde, which contains a hydrogen atom at the γ-position an amine-aldehyde-dienophile (AAD) [4+2] cycloaddition takes place by formation of an intermediate 1-amino-1,3-diene affording highly functionalized cyclohexenes with high endo-diastereoselectivity. This AAD process only occurred when a nitro group is bonded to the 4-position of the initial enantiomerically enriched pyrrolidine ring. DFT calculations have been done with the aim to explain this different behavior between pyrrolidines bearing or not a nitro group demonstrating the strongly nitro group-dependent
periselectivity. The results of these computational studies also support the experimentally obtained absolute configuration of the final adducts.

INTRODUCTION

Diversity-oriented synthesis (DOS) concept described by Schreiber \(^1\) has been interestingly applied in many methodologies for the synthesis of complex molecules. The formation of molecular frameworks, just by modifying functional group arrangements, reaction parameters, etc., are key features of divergent synthesis. In this concept, the addition of operational simplicity and atom (and step) economy provided by multicomponent reactions (MCRs) \(^2\) constitutes a very important strategy. Particularly, 1,3-dipolar cycloadditions (1,3-DC) \(^3,4\) and amide-aldehyde-dienophile (AAD) \(^5\) are attractive and versatile multicomponent processes that can generate organic molecules with very different skeletons.

We and other groups have recently described that 1,3-DC of \textit{in situ} generated cyclic azomethine ylides could be used for the generation of highly substituted

![Chemical structures](image-url)
pyrrolizidines, and indolizidines. Namely, pyrrolizidine alkaloids are currently of special interest because they have wide and interesting biological properties. These heterocycles 2 can be obtained by multicomponent reaction of proline derived esters 1 with aromatic, aliphatic, and α,β-unsaturated aldehydes, and the corresponding dipolarophiles. Mild reaction conditions were required for all type of electrophilic alkenes affording diastereoselectively bicyclic alkaloids 2 in good yields (Scheme 1, eq a).

On the other hand, the MCR known as AAD has been widely studied for the synthesis of 3-aminocyclohexenes and other interesting structures. Amides, carbamates and sulfonamides reacted with aldehydes and dienophiles in the presence of TsOH through a [4+2] process, to yield the corresponding cycloadducts 3 (Scheme 1, eq b). These AAD reactions have provided the access to several hetero- and carbocycles as well as key structural cores of the natural product pumiliotoxin C.

Scheme 1. a) General multicomponent 1,3-DC of prolinates, aldehydes and dipolarophiles affording pyrrolizidines 2. b) General multicomponent [4+2]
cycloaddition of amides-aldehydes-dienophiles (AAD processes) providing 3-aminocyclohexenes 3.

Concerning the presence of a nitro group in cyclic structures\textsuperscript{12} not only allows a series of synthetic transformations but also enhances/modifies the biological properties of such molecules. Thus, optically active polysubstituted nitroprolinates have emerged as promising therapeutic agents. For example, molecules 4 (Figure 1) are important inhibitors of $\alpha_4\beta_1$-integrin-mediated hepatic melanoma and in a murine model of colon carcinoma metastasis, as well as potent antiadhesive properties in several cancer cell lines.\textsuperscript{13,14} Bicyclic heterocycles 5, containing an atropane scaffold have been found as novel inhibitors of skin cancer.\textsuperscript{15} Spiroxindoles 6 increased the mortality of zebrafish embryos,\textsuperscript{16} whilst molecules 7 with benzopyran skeleton were successfully tested as antimycobacterials against M. tuberculosis H37Rv strain. 4-Nitroprolines $\textit{exo}$-8, and $\textit{endo}$-8 have been recently used as chiral organocatalysts in aldol reactions.\textsuperscript{17} Michael-type addition of ketones to nitroalkenes was successfully organocatalyzed by $\textit{exo}$-$\textit{8b}$ (X=H),\textsuperscript{18} providing good to excellent diastereoselections and high enantiomeric ratios. A series of enantiopure tetrasubstituted nitroproline surrogates has been designed as scaffolds for proteasome inhibitors with high medicinal prospects.\textsuperscript{19} In addition, the NH-D-EhuPhos ligand 9 has been efficiently employed in the 1,3-dipolar cycloadditions (1,3-DC) to yield nitroprolines and structurally rigid spirocompounds from chiral $\gamma$-lactams.\textsuperscript{17,20,21} A family of enantiomerically enriched spironitroprolinates 10 were obtained by our group from imino lactones and nitroalkenes which are currently tested as anticancer agents.\textsuperscript{22}
Figure 1. Interesting nitroprolinates with biological properties and with useful synthetic applications.

Continuing with our interest in the enantioselective synthesis of nitroprolinates and their synthetic applications, we described here the periselectivity exhibited by enantiopure nitroprolinates towards 1,3-DC or AAD processes in the reaction with α,β-unsaturated aldehydes and electrophilic alkenes.

RESULTS AND DISCUSSION

During initial studies of the multicomponent 1,3-DC involving enantioenriched nitroprolinates exo-1a, prepared from methyl benzylidenglycinate and β-nitrostyrene, in the presence of a chiral phosphoramidite·AgOBz complex (5 mol%) in >99:1 er (>99:1 exo:endo dr),23,24 with α,β-unsaturated aldehydes and dipolarophiles, using a conventional iminium route, we detected the formation of different final products depending on the structure of the α,β-unsaturated aldehyde. Thus, in the absence of hydrogens at the γ-position of the aldehyde (e.g. cinnamaldehyde) the expected pyrrolizidine 2a was formed (as a 73:27 endo:exo mixture of diastereoisomers in 96%
yield) employing N-methylmaleimide (NMM) as dipolarophile and silver acetate (5 mol%) as catalyst (Scheme 2, eq a, and Table 1, entry 1). However, crotonaldehyde, which incorporates hydrogen atoms at the γ-position, afforded product 3a (>99:1 dr in 94% yield) acting NMM as dienophile (Scheme 2, eq b). In this last case, an amine (instead of amide)-aldehyde-dienophile (AAD) multicomponent process took place through the intermediate 1-pyrrolidine-1,3-diene formed by a previous isomerization of the iminium ion. Apart from amides, a few examples of AAD using pyrrolidine, morpholine, proline derivatives or diallylamine have been reported. In the last case only nitrostyrenes were used as dienophiles.

Scheme 2. Divergent multicomponent synthesis of pyrrolizidines endo- and exo-2a via 1,3-DC or polysubstituted cyclohexenes 3a via AAD process from prolinate exo-1a, aldehydes and NMM.

To study the scope of the 1,3-DC, cinnamaldehyde was selected as aldehyde, for the reaction with prolinate exo-1a and different dipolarophiles at 70 °C in the presence of AgOAc (5 mol%) generating enantiomerically enriched pyrrolizidines 2a-h in good chemical yields (up to 96%, Scheme 3 and Table 1, entries 1-8). Apart from NMM, maleimide was a suitable dipolarophile in this reaction affording a 68:32 endo-2b:exo-
2b mixture in combined excellent yield (95%) (Table 1, entry 2). A very high regioselectivity and endo-diastereoselectivity were observed in the case of the 1,3-DC performed with methyl acrylate obtaining endo-2d in 88% yield (Table 1, entry 4). Methyl fumarate furnished a 65:35 mixture of endo/exo adducts in 74% yield, the corresponding endo-cycloadducts 2e being the major diastereoisomer (Table 1, entry 5). In the specific reaction with dialkyl acetylenedicarboxylates large quantities of 1,4-addition products of the nitroprolinate onto the electron-deficient alkyne were observed furnishing the desired 2f or 2g products as unique diastereoisomers in modest yields (Table 1, entries 6 and 7).

β-Phenylcinnamaldehyde was also tested as generator of the iminium salt in the presence of N-phenylmaleimide (NPM). endo-Cycloadduct 2h was isolated in moderate yield as 74:26 dr (Table 1, entry 8). This result contrasted with the major exo-selectivity (26:74 or 32:68) detected for the reaction of the same NPM with cinnamaldehyde and both nitroprolinate exo-1a or exo-1b, respectively (Table 1, entries 3 and 9). This unexpected and exceptional behavior of NPM will be discussed later.

Relative configurations of these molecules were determined in the basis of 1H NMR data and from nOe experiments and also by comparison with similar enantioenriched cycloadducts previously reported. The diastereomeric ratios observed in the crude mixtures (determined by 1H NMR analysis) were very similar to those obtained after separation of both diastereoisomers, which could be separated by flash chromatography (see, experimental section). Besides, these assignments are in perfect agreement with the absolute configuration revealed by X-ray diffraction analysis of molecule endo-2a (see, supporting information and Scheme 3).

The reactions performed with aliphatic or aromatic aldehydes instead of using α,β-unsaturated aldehydes, gave poor conversions of the expected pyrrolizidines. The
employment of dipolarophiles such as nitroalkenes, vinyl sulfoxides, and chalcones under these conditions was not satisfactory.

Scheme 3. Synthesis of pyrrolizidines 2 via 1,3-DC from prolinate \textit{exo-1a}, cinnamaldehyde derivatives with different dipolarophiles and X-ray diffraction analysis of compound \textit{endo-2a}.

ACS Paragon Plus Environment
Enantiomerically enriched *endo-*1a (85:15 er and >99:1 dr), obtained from the starting materials employed for the preparation of compound *exo-*1a but using a catalyst formed by NH-D-EhuPhos 9 and Cu(MeCN)₄PF₆,¹⁷,²⁰ was not so useful precursor to run this multicomponent process giving 2j as 50/50 *endo/*exo dr, in very low yield (<20% from crude ^1^H NMR spectra, Scheme 4). However, racemic *endo-*prolinate 1c, obtained according to the procedure described for *exo-*1a and from the corresponding nitroalkene, afforded 2k as pure racemic *endo-*stereoisomer, in 72% yield (Scheme 4). Yields represented in Scheme 4 obey to the overall yields obtained after purification as well as their corresponding dr. In the reaction of nitroprolinate *endo-*1a, both diastereoisomers *endo-* and *exo-*2j could not be separated by flash chromatography (see, experimental section).

In these examples, as well as in the described in entries 3 and 9 of Table 1, NPM approached to the dipole with an *exo*-orientation. The driving force that causes *exo* preference can be attributed to a lower destabilizing stereoelectronic interaction, mainly consisted of electrostatic repulsion between the nitro group of the dipole and the phenyl group of the dipolarophile, compared with the *endo* approach (see below in Figure 2, in the explanation of the periselectivity of these reactions). In contrast, the presence of an additional phenyl moiety of β-phenylecinnamaldehyde implies a higher Pauli repulsion in the *exo*-approach, which makes this approximation less favorable. In consequence, in this case *endo-*2h adduct was the major diastereoisomer obtained.
Scheme 4. Pyrrolizidines 2j and 2k obtained from endo-nitroprolinates 1 with cinnamaldehyde and NPM.

AAD reactions of compound exo-1a (>99:1 er, >99:1 dr) with crotonaldehyde and maleimides were carried out at room temperature. The reaction with NMM (2 equiv) gave compound 3a in a very high yield (94%) and also NPM, N-benzylmaleimide, maleimide and maleic anhydride gave satisfactory yields (86%, 89%, 80%, and 71% respectively) of products 3b-3e (Scheme 5). 1,4-Benzquinone afforded compound 3f in 65% yield (determined by $^1$H NMR spectra of the crude product) at room temperature. Higher temperature (70 ºC) was needed to accomplish the reaction with 1,2-bis-(phenylsulfonyl)ethylene (BPSE) giving compound 3g in 78% yield. Diisopropyl azodicarboxylate also promoted the multicomponent AAD reaction giving
Diastereomeric compounds 3f and 3h could not be neither purified by column chromatography due to partial decomposition nor recrystallized in order to obtain pure samples to accomplish the full characterization. Next, α,β-unsaturated aldehydes with hydrogen atoms at the γ-position such as 3-methyl-2-butenal, 2-pentenal and 2-hexenal were appropriate aldehydes for the success of the name AAD multicomponent reaction furnishing with NPM adducts 3i, 3j and 3k in 62%, 89%, and 72%, respectively (Scheme 5). In all these examples, aminocyclohexenes 3 were isolated as unique diastereoisomers. However, the reaction with geraniol, NPM and nitroproline exo-1a gave a complex crude mixture containing the major adduct 3l and various unidentified compounds. After purification, only a 53% yield of the product 3l could be isolated.

Compounds 3 were obtained in excellent dr affording enantiomerically pure cycloadducts after flash chromatography, except compounds 3f and 3h as mentioned above. In the case of the cycloadduct 3e, derived from maleic anhydride, it was obtained after chromatographic purification as a 63:37 mixture of diastereoisomers, the structure of the major compound being drawn in Scheme 5. The absolute configuration of new compound 3b was unambiguously established by X-ray diffraction analysis (see, Supporting Information and Scheme 5). For other molecules 3 complementary 1H NMR analysis also confirmed the drawn structures depicted in Scheme 5.

![Scheme 5](image-url)
Scheme 5. Polyfunctionalized cyclohexenes 3 obtained from AAD employing nitropolinate \( \text{exo-1a} \), \( \alpha,\beta \)-unsaturated aldehydes with hydrogen atoms at the \( \gamma \)-position and dienophiles and X-ray diffraction analysis of compound 3b.
Two nitroprolinates, \textit{exo-1b} and \textit{rac-endo-1c} were tested as precursors in this AAD domino reaction with NPM and crotonaldehyde. The reaction of the \textit{exo-1b} gave \textit{3m} in 81\% yield, whereas \textit{rac-endo-1c} afforded compound \textit{3n} as a 1:1 mixture of two inseparable diastereoisomers in 79\% overall yield (Scheme 6).

\begin{center}
\includegraphics[width=0.8\textwidth]{scheme6.png}
\end{center}

\textbf{Scheme 6}. Products \textit{3m} and \textit{3n} obtained from AAD sequence employing different \textit{exo} and \textit{endo}-nitroprolinates with crotonaldehyde and NPM.

Noteworthy, no AAD multicomponent reaction was observed during the reaction of L-proline methyl ester \textit{11} or proline ester derivatives \textit{12, 13} and \textit{14}. In these cases,
the 1,3-DC occurred instead and the corresponding *endo-*pyrrolizidines 15-18 were formed in 61%, 69%, 67% and 68% yield, respectively (Scheme 7).

**Scheme 7.** Products *endo*-15-18 obtained from 1,3-DC employing different methyl prolinates with crotonaldehyde and NPM.

According to these described results, the presence of the nitro group is crucial in the origin of the periselectivity in these multicomponent reactions. Thus, the effect of the presence and absence of the nitro group in the starting prolinate derivatives *exo*-1a, 11, *endo*-13 and *endo*-14 (derived from dimethyl fumarate) in the reaction outcome was next analyzed by means of DFT calculations. We selected the reactions of NMM, crotonaldehyde and proline derived esters with different substitution patterns in order to shed light on the observed periselectivity of each reactive system between the [4+2] AAD multicomponent reaction or the pyrrolizidine synthesis via 1,3-DC.
The initial step in the proposed mechanism consists in the formation of the iminium cation A, derived from the condensation between the proline derivative and crotonaldehyde (Scheme 8). This intermediate has two acidic protons. Therefore, in presence of a base, A can evolve into the azomethine ylide B by abstraction of the hydrogen atom located in α-position of the methoxycarbonyl group, that leads to pyrrolizidines 2, 15-18 or to a dienamine intermediate C by abstraction of the hydrogen atom in γ-position of crotonaldehyde, thus forming cyclohexenylpyrroldines 3.
Scheme 8. General scheme of the reaction of prolinates, aldehydes and dipolarophiles affording pyrrolizidines 2 or cyclohexenylpyrrolidines 3. Acidic positions are highlighted.

According to the Fukui frontier molecular orbital (FMO) theory, \( \pi 4s + \pi 2s \) cycloaddition reactions are mainly governed by symmetry allowed \( \text{HOMO}_{\text{dipole/diene}} \)–\( \text{LUMO}_{\text{dipolarophile/dienophile}} \) interactions. Within this framework, small energy gap \( \Delta E_{\text{HOMO-LUMO}} \) is related to a high reactivity. Inspection of the reagent FMOs shown that the less stable azomethine ylides B seem to be more reactive than dienamines C, regardless the proline derivative 1 used (see, Supporting Information). As a consequence of this reactivity-stability dichotomy, in which unstable reagents are the most reactive ones, exploration of all the possible transition states associated with the formation of pyrrolizidines 2, 15-18 and cyclohexenyl pyrrolidines 3 was carried out. Nevertheless, if we assume a pre-equilibrium between all the possible reactive species, Curtin-Hammet kinetics show that the product ratio depends on the free Gibbs activation energy difference of the corresponding transition structures. The relative Gibbs free energies and main geometrical features of the less energetic computed transition states are shown in Figures 2-4. As far as nitroproline \textit{exo}-1a is considered, our calculations show that the transition structure associated with the AAD multicomponent reaction (\( \text{TS}_{\text{AAD-exo-1a}} \)) is 1.2 kcal mol\(^{-1}\) more stable than its 1,3-DC analog \( \text{TS}_{\text{1,3-DC-exo-1a}} \) (Figure 2). Therefore, cyclohexenylpyrrolidines 3 will be preferentially formed in this case, despite the higher reactivity of dipole B. The computed energetic difference between all the possible transition structures \( \text{TS}_{\text{AAD}} \) associated with formation of cyclohexenylpyrrolidines 3 (especially those comparing the \textit{endo-} and the \textit{exo-}
approach) show a theoretical dr of c.a. 99:1, in perfect agreement with the experimental results (see, Supporting Information).

Analysis of the geometries depicted in Figure 2 also supports a diastereofacial bias in highly substituted nitroproline $\text{exo-1a}$ derived transition state, where substituents in position 2, 3 and 5 effectively block one face of the azomethine ylide or the aminodiene intermediate. Therefore, in $\text{TS_{1,3-DC-exo-1a}}$ the dipolarophile has to approach towards the dipole by the nitro group face. Within this approach, high Pauli repulsions between the dipolarophile and the nitro group are expected (Figure 2). These stereoelectronic effects are reflected in the high energy required to deform the azomethine ylide $\text{B}$ from its relaxed geometry to the one that adopts in the transition state structure, making the 1,3-DC energetically inaccessible, and thus converting the low-distorted AAD reaction the preferred one (see the distortion/interaction analysis\textsuperscript{33} in the Supporting Information). Regarding these Pauli repulsions, is it plausible to assume that they are the responsible of the favorable $\text{exo}$-approach of NPM in the course of 1,3-DCs.
Figure 2. Relative Energies, Gibbs free energy (between parenthesis) and main geometrical features of the most stable transition structures associated with the 1,3-DC (TS\textsubscript{1,3-DC}\textsubscript{exo-1a}) or multicomponent AAD (TS\textsubscript{AAD}\textsubscript{exo-1a}) associated with the reaction of crotonaldehyde, NMM and exo-1a (A) computed at B3LYP/6-31G* level of theory and M06-2X/6-31G*/B3LYP/6-31G* level of theory (in italics and between brackets, respectively) at 298K. Distances and energies are in Å and in kcal mol\(^{-1}\), respectively.

On the other hand, the employment of proline derivatives 11 (Scheme 7) implies a change in the periselectivity of the reaction. In this example, preferential formation of pyrrolizidine 15 was observed, being TS\textsubscript{1,3-DC} (associated with the 1,3-DC) c.a. 3 kcal mol\(^{-1}\) more stable than their TS\textsubscript{AAD} counterpart, in good agreement with the
periselectivity observed experimentally (Figure 3). A detailed inspection of the geometries shows that generation of reactive azomethine ylides B (Scheme 8) forces the pyrrolidine ring (and in consequence the iminium ion A) into a planar conformation in which all substituents are placed in an isoclinal position. Within this fixed conformation, the substituents can effectively block one or both faces of the azomethine ylide. Therefore, it was observed that an small additional energy is required for the deformation of the azomethine ylide during an endo-approach, increasing the activation barrier associated with the 1,3-DC. But never this increment generates a TS$_{1,3\text{-DC}}$ with higher energy than the corresponding TS$_{AAC}$ one (14.4 kcal mol$^{-1}$ and 18.7 kcal mol$^{-1}$, respectively). Thus, a strong preference for the 1,3-DC is observed.
**Figure 3.** Relative Gibbs free energy and main geometrical features of the most stable transition structures associated with the 1,3-DC (TS\textsubscript{1,3-DC-11}) or multicomponent AAD (TS\textsubscript{AAD-11}) associated with the reaction of crotonaldehyde, NMM and (B) proline 11. See caption of Figure 2 for further details.

However, in dienamine intermediates (Figure 4, A and B) the pyrrolidine ring has a twist conformation where most of the substituents are placed in an equatorial position. In these both examples, the steric hindrance is considerably lower than in the former TS\textsubscript{AAD-11}, and therefore, the activation barrier is less influenced by the substituents (Figure 4).

For the maleimide derivative *endo*-13, the *cis*-substitution pattern in the pyrrolidine ring leads to the effective blockage of only one of the prochiral faces, and low distortion of the initial reagent is required for the attack to the less hindered face. Therefore, in this case, 1,3-DC was preferred over multicomponent AAD process such as it was observed for L-proline methyl ester 11. In consequence, formation of pyrrolizidine 17 is theoretically expected. In the case of fumaric ester derivative 14, despite having a *trans*-substitution pattern that should block both prochiral faces of azomethine ylide in a similar way to *exo*-1a, the steric requirements of the methoxycarbonyl groups are smaller than phenyl or nitro substituents, and the energy required to distort the initial azomethine ylide is lower. In fact, the transition structure associated with the 1,3-DC (TS\textsubscript{1,3-DC-endo-14}) was found to be 3.6 kcal mol\(^{-1}\) more stable than that of its AAD counterpart (TS\textsubscript{AAD-endo-14}). Preferential formation of pyrrolizidines 15-18 are theoretically assessed when 11-14 are used as starting materials.
**Figure 4.** Relative Gibbs free energy and main geometrical features of the most stable transition structures associated with the 1,3-DC (TS\textsubscript{1,3-DC-endo-13} and TS\textsubscript{1,3-DC-endo-14}) or multicomponent AAD (TS\textsubscript{AAD-endo-13} and TS\textsubscript{AAD-endo-14}) associated with the reaction of crotonaldehyde, NMM and (A) endo-13, or (B) endo-14. See caption of Figure 2 for further details.

**CONCLUSION**

An example of total periselectivity has been demonstrated in the multicomponent 1,3-DC or AAD of enantiopure methyl exo- or endo-4-nitroprolinates in the presence of a dipolarophile and an α,β-unsaturated aldehyde. The crucial presence of a nitro group in the heterocycle and the existence or not of hydrogen atoms at the γ-position of the aldehyde determines the periselectivity towards AAD or 1,3-DC, respectively. The diastereomeric control was notable in the [3+2] process and excellent in [4+2] cycloadditions affording in this last case enantiopure polysubstituted 3-aminocyclohexenes. On the basis of the DFT calculations here presented, it was supported that azomethine ylides derived from proline derivatives and crotonaldehyde are in general more reactive than its dienamine counterparts, being the 1,3-DC preferred over the AAD reaction. Only in the case of highly hindered azomethine ylides, such as the one derived from exo-1a, 1,3-DC is hindered due to the huge energy required to distort the reagents into the transition structure geometry. Therefore, the less reactive dienamine takes importance, being the AAD pathway the only one energetically
accessible. The evaluation of all these series of molecules as anticancer agents are currently underway.

**EXPERIMENTAL SECTION**

*General Experimental Methods:* All commercially available reagents and solvents were used without further purification, only aldehydes were also distilled prior to use. Analytical TLC was performed on Schleicher & Schuell F1400/LS 254 silica gel plates, and the spots were visualised under UV light ($\lambda = 254$ nm). Flash chromatography was carried out on handpacked columns of Merck silica gel 60 (0.040-0.063 mm). Melting points were determined with a Reichert Thermovar hot plate apparatus and are uncorrected. Optical rotations were measured on a Perkin Elmer 341 polarimeter with a thermally jacketted 5 cm cell at approximately 25 ºC and concentrations ($c$) are given in g/100 mL. The structurally most important peaks of the IR spectra (recorded using a Nicolet 510 P-FT) are listed and wavenumbers are given in cm$^{-1}$. NMR spectra were obtained using a Bruker AC-300 or AC-400 and were recorded at 300 or 400 MHz for $^1$H NMR and 75 or 100 MHz for $^{13}$C NMR, using CDCl$_3$ as solvent and TMS as internal standard (0.00 ppm). The following abbreviations are used to describe peak patterns where appropriate: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet or unresolved and br s = broad signal. All coupling constants ($J$) are given in Hz and chemical shifts in ppm. $^{13}$C NMR spectra were referenced to CDCl$_3$ at 77.16 ppm. DEPT-135 experiments were performed to assign CH, CH$_2$ and CH$_3$. Low-resolution electron impact (EI) mass spectra were obtained at 70 eV using a Shimadzu QP-5000 by injection or DIP; fragment ions in $m/z$ are given with relative intensities (%) in parentheses. High-resolution mass spectra (HRMS) were measured on
an instrument using a quadrupole time-of-flight mass spectrometer (QTOF) and also through the electron impact mode (EI) at 70 eV using a Finnigan VG Platform or a Finnigan MAT 95S.

Computational methods: All the computational mechanistic studies were carried out with the Gaussian09 \textsuperscript{34} suite of programs. Density functional Theory (DFT) geometry optimizations and harmonic analysis were preformed with the B3LYP\textsuperscript{35} functional. Relative energies were computed by means of single-point calculations on the optimized geometries with the M06-2X\textsuperscript{36} functional. This latter functional was chosen because it is well suited for the treatment of nonbonding interactions and dispersion forces in densely substituted interacting systems\textsuperscript{37} and produce similar geometries to B3LYP,\textsuperscript{38} although it tends to slightly overestimate the barriers of hetero Diels Alder reactions.\textsuperscript{39}

The 6-31G* basis set was used. Solvent effects were computed with the PCM method using toluene as solvent.\textsuperscript{40} All the stationary points were characterized by harmonic analysis. Reactants, intermediates and products showed positive definite Hessian values. Transition structures (TSs) showed one and only one imaginary frequency associated with nuclear motion along the chemical transformation. Activation and reaction (Gibbs) energies were calculated at 298.15 K. Figures including optimized structures were made with Maestro\textsuperscript{41} and CYL-view\textsuperscript{42} programs. Orbital diagrams were prepared by using the Gauss-view interface.\textsuperscript{43}

General procedure for the synthesis of pyrrolizidines \textit{2a-2k}: To a stirred solution of the nitroprolinate 1 (0.1 mmol) in toluene (1 mL) the aldehyde (0.1 mmol) and the dipolarophile (0.1 mmol) were added. Then a 5 mol\% of AgOAc (0.005 mmol, 0.84
mg) was added and the reaction was stirred overnight at 70 °C in the dark. Then the reaction was filtered through a celite path and the solvent was evaporated under reduced pressure. The crude mixture was purified by flash column chromatography over silica gel (20% EtOAc in hexane as the eluent) to furnish the corresponding product 2.

Methyl (3aS,4S,6S,7R,8R,8aR,8bR)-2-methyl-7-nitro-1,3-dioxo-6,8-diphenyl-4-((E)-styryl)octahydropyrrolo[3,4-a]pyrrolizine-8a(6H)-carboxylate (endo-2a): The representative procedure was followed by using exo-nitroprolinate 1a (0.1 mmol, 32.6 mg), cinnamaldehyde (0.1 mmol, 12.6 µL) and N-methylmaleimide (0.1 mmol, 11.1 mg). The desired product was obtained as colorless prisms (38.6 mg, 70% yield), mp 194-197 °C (Et₂O), [α]D²⁻³⁸ = +160.3 (c 1.0, CHCl₃), IR (neat) νmax: 1742, 1697, 1552, 1208, 1037, 968 cm⁻¹. ¹H NMR δ: 3.19 (s, 3H), 3.30 (s, 3H), 3.53 (t, J = 8.0 Hz, 1H), 4.20 (dd, J = 10.2, 8.0 Hz, 1H), 4.34 (d, J = 8.0 Hz, 1H), 4.69 (d, J = 8.4 Hz, 1H), 4.86 (d, J = 9.9 Hz, 1H), 5.41 (dd, J = 9.9, 8.4 Hz, 1H), 5.89 (dd, J = 15.5, 10.2 Hz, 1H), 6.31 (d, J = 15.5 Hz, 1H), 6.82-6.91 (m, 2H), 7.13-7.49 (m, 13H). ¹³C NMR δ: 25.6, 52.0, 52.1, 52.7, 52.8, 64.9, 67.9, 82.7, 96.7, 122.6, 126.7, 126.9, 128.1, 128.3, 128.4, 128.8, 128.9, 129.0, 134.8, 135.8, 136.0, 139.0, 171.4, 175.6, 176.8. MS (EI) m/z: 551 (M⁺, <1%), 505 (41), 492 (59), 446 (32), 445 (100), 256 (29), 193 (61), 115 (58), 91 (25). HRMS calculated for C₃₂H₂₉N₃O₆: 551.2056; found: 551.2057.

Methyl (3aR,4S,6S,7R,8R,8aR,8bS)-2-methyl-7-nitro-1,3-dioxo-6,8-diphenyl-4-[(E)-styryl]octahydropyrrolo[3,4-a]pyrrolizine-8a(6H)-carboxylate (exo-2a): This minor product was obtained as colorless plates (14 mg, 26% yield), mp 88-90 °C (Et₂O), [α]D²⁻⁹⁹ = +76.1 (c 0.5, CHCl₃), IR (neat) νmax: 1737, 1700, 1551, 1434, 1372, 1279, 1131, 1084, 968 cm⁻¹. ¹H NMR δ: 3.04 (s, 3H), 3.23 (s, 3H), 3.82 (dd, J = 9.9, 6.6 Hz, 1H), 4.15 (d, J = 9.9 Hz, 1H), 4.48 (dd, J = 7.9, 6.6 Hz, 1H), 4.56 (d, J = 8.9 Hz, 1H), 4.83 (d, J = 7.6 Hz, 1H), 5.44 (dd, J = 8.9, 7.6 Hz, 1H), 5.90 (dd, J = 15.7, 7.9 Hz, 1H), 6.53
Methyl (3aS,4S,6S,7R,8R,8aR,8bR)-7-nitro-1,3-dioxo-6,8-diphenyl-4-[(E)-styryl]octahydropyrrolo[3,4-a]pyrrolizine-8a(6H)-carboxylate (endo-2b): The representative procedure was followed by using exo-nitroprolinate 1a (0.1 mmol, 32.6 mg), cinnamaldehyde (0.1 mmol, 12.6 µL) and maleimide (0.1 mmol, 9.7 mg). The desired product was obtained as pale pink prisms (3.5 mg, 65% yield), mp 249–252 °C (Et₂O), [α]D²⁶ = +179.2 (c 1.0, CHCl₃), IR (neat) νmax: 1711, 1554, 1356, 1192, 750 cm⁻¹. ¹H NMR δ: 3.33 (s, 3H), 3.57 (t, J = 8.3 Hz, 1H), 4.21 (dd, J = 10.3, 8.5 Hz, 1H), 4.37 (d, J = 8.2 Hz, 1H), 4.91 (d, J = 8.4 Hz, 1H), 5.01 (d, J = 10.2 Hz, 1H), 5.50 (dd, J = 10.2, 8.4 Hz, 1H), 5.93 (dd, J = 15.4, 10.3 Hz, 1H), 6.28 (d, J = 15.4 Hz, 1H), 6.84–6.91 (m, 2H), 7.10–7.50 (m, 13H), 8.67 (br s, 1H). ¹³C NMR δ: 25.3, 52.3, 53.0, 56.0, 58.0, 65.7, 68.2, 82.9, 97.3, 125.4, 126.7, 127.2, 128.1, 128.2, 128.5, 128.8, 129.0, 129.2, 134.8, 135.5, 135.8, 139.4, 169.2, 174.5, 175.8. MS (EI) m/z: 551 (M⁺, <1%), 506 (19), 505 (55), 492 (18), 446 (17), 445 (48), 256 (19), 194 (18), 193 (100), 115 (57), 91 (21). HRMS calculated for C₃₂H₂₉N₂O₄ [M–NO₂]: 505.2127; found: 505.2129.

Methyl (3aR,4S,6S,7R,8R,8aR,8bS)-7-nitro-1,3-dioxo-6,8-diphenyl-4-[(E)-styryl]octahydropyrrolo[3,4-a]pyrrolizine-8a(6H)-carboxylate (exo-2b): This minor product was obtained as yellow prisms (16.2 mg, 30% yield), mp 108–111 °C (Et₂O), [α]D²⁶ = +81.3 (c 1.0, CHCl₃), IR (neat) νmax: 1712, 1552, 1340, 1180, 737 cm⁻¹. ¹H
NMR δ: 3.27 (s, 3H), 3.83 (dd, J = 9.9, 7.6 Hz, 1H), 4.14 (d, J = 9.9 Hz, 1H), 4.51 (d, J = 8.6 Hz, 1H), 4.50-4.56 (m, 1H), 4.76 (d, J = 7.7 Hz, 1H), 5.37 (dd, J = 8.6, 7.7 Hz, 1H), 5.84 (dd, J = 15.7, 7.7 Hz, 1H), 6.51 (d, J = 15.7 Hz, 1H), 6.81-6.92 (m, 2H), 7.11-7.46 (m, 13H), 8.36 (br s, 1H).

mmol, 17.3 mg). The desired product was obtained as yellow plates (33.8 mg, 53% yield), mp 117-120 °C (Et₂O), [α]D²⁴ = +34.3 (c 0.6, CHCl₃), IR (neat) νmax: 1743, 1703, 1549, 1375, 1163, 750 cm⁻¹. ¹H NMR δ: 1.54 (s, 3H), 1.64 (s, 3H), 1.93-2.10 (m, 5H), 2.67 (dd, J = 15.0, 1.9 Hz, 1H), 3.18 (ddd, J = 9.0, 7.2, 1.9 Hz, 1H), 3.30 (s, 3H), 3.56 (dd, J = 9.0, 6.8 Hz, 1H), 3.69 (br s, 1H), 4.44 (d, J = 9.4 Hz, 1H), 4.97 (dd, J = 12.0, 9.4 Hz, 1H), 4.97-5.03 (br s, 1H), 5.25 (d, J = 8.5 Hz, 1H), 5.45 (br s, 1H), 5.61 (dd, J = 12.0, 8.5 Hz, 1H), 7.20-7.33 (m, 7H), 7.41-7.56 (m, 6H), 7.66-7.71 (m, 2H). ¹³C NMR δ: 17.8, 25.8, 25.9, 27.9, 37.2, 39.2, 39.6, 50.9, 51.9, 54.0, 66.0, 68.4, 92.5, 120.6, 123.2, 126.6, 127.8, 128.1, 128.7, 129.0, 129.4, 129.5, 132.0, 132.5, 133.0, 137.9, 142.0, 174.5, 177.2, 178.4. MS (EI) m/z: 634 (M⁺, <1%), 279 (27), 278 (100), 240 (13), 220 (37), 115 (15), 91 (18), 69 (17). HRMS calculated for C₃₈H₆₀N₂O₄ [M–NO₂]: 587.2910; found: 587.2895.

**Methyl (2R,3S,4R,5S)-1-[(3aS,4R,7aS)-1,3-dioxo-2-phenyl-2,3,3a,4,7,7a-hexahydro-1H-isooindol-4-y]-3-(4-methoxyphenyl)-4-nitro-5-diphenylpyrrolidine-2-carboxylate (3m):** The representative procedure was followed by using exo-nitroprolinate 1b (0.1 mmol, 35.6 mg), crotonaldehyde (0.1 mmol, 8.3 µL) and N-phenylmaleimide (0.1 mmol, 17.3 mg). The desired product was obtained as orange prisms (47.2 mg, 81% yield), mp 208-211 °C (Et₂O), [α]D²⁵ = +86.3 (c 1.0, CHCl₃), IR (neat) νmax: 1745, 1702, 1550, 1517, 1388, 1254, 1156, 1024, 796, 761 cm⁻¹. ¹H NMR δ: 1.93-2.04 (m, 1H), 2.80 (ddd, J = 15.7, 7.0, 1.7 Hz, 1H), 3.18 (ddd, J = 9.0, 7.5, 1.7 Hz, 1H), 3.36 (s, 3H), 3.60 (dd, J = 9.0, 7.0 Hz, 1H), 3.71 (dd, J = 6.6, 3.0 Hz, 1H), 3.75 (s, 3H), 4.40 (d, J = 9.3 Hz, 1H), 4.90 (dd, J = 12.1, 9.3 Hz, 1H), 5.23 (d, J = 8.5 Hz, 1H), 5.54 (dd, J = 12.1, 8.5 Hz, 1H), 5.84 (dt, J = 9.7, 3.0 Hz, 1H), 5.98 (ddt, J = 10.0, 6.6, 3.0 Hz, 1H), 6.76-7.31 (m, 6H), 7.39-7.56 (m, 6H), 7.65-7.69 (m, 2H). ¹³C NMR δ: 23.9, 39.0, 39.6, 50.4, 52.0, 53.4, 55.3, 66.0, 68.2, 93.0, 114.1, 124.7, 126.7, 127.7,
Methyl (2S*,3R*,4S*,5S*)-1,3-dioxo-2-phenyl-2,3a,4,7a-hexahydro-1H-isoindol-4-yl]-4-nitro-5-phenylpyrrolidine-2-carboxylate (3n): The representative procedure was followed by using rac-endo-nitroprolinate 1c (0.1 mmol, 33.2 mg), crotonaldehyde (0.1 mmol, 8.3 µL) and N-phenylmaleimide (0.1 mmol, 17.3 mg). The desired product was obtained as colorless prisms (26.5 mg, 79% yield), mp 76-80 °C (Et2O), IR (neat) νmax: 1705, 1551, 1380, 1166 cm−1. 1H NMR δ [mixture of diastereoisomers (1:1)]: 0.75-0.94 (m, 4H), 0.98-1.18 (m, 8H), 1.51-1.81 (m, 12H), 1.96-2.14 (m, 1H), 2.69-2.93 (m, 1H), 3.07-3.22 (m, 1H), 3.30 (dd, J = 10.8, 4.3 Hz, 1H), 3.44 (ddd, J = 11.3, 9.7, 5.8 Hz, 1H), 3.60 (dd, J = 9.1, 8.0 Hz, 1H), 3.80-4.00 (m with 2s at 3.82 and 3.90, 9H), 4.29 (d, J = 9.6 Hz, 1H), 4.75 (d, J = 9.4 Hz, 1H), 5.21 (d, J = 9.1 Hz, 1H), 5.34 (dd, J = 9.1, 8.3 Hz, 1H), 5.58-5.66 (m, 2H), 5.71-5.80 (m, 1H), 5.85 (dt, J = 10.0, 2.8 Hz, 1H), 5.90-5.99 (m, 1H), 7.21-7.65 (m, 20H). 13C NMR δ [mixture of diastereoisomers (1:1)]: 22.8, 23.4, 26.1, 26.4, 29.8, 30.1, 30.4, 30.7, 38.6, 38.8, 39.2, 39.4, 40.6, 48.4, 51.5, 52.5, 52.7, 54.7, 55.1, 64.0, 66.1, 68.0, 89.3, 90.5, 126.5, 127.6, 128.3, 128.5, 128.7, 128.9, 129.1, 129.2, 129.5, 137.2, 140.6, 173.6, 175.9, 176.7, 177.1, 178.4. MS (EI) m/z: 557 (M+, <1%), 512 (35), 511 (100), 498 (22), 451 (22), 384 (38), 337 (37), 331 (40), 286 (57), 284 (26), 278 (46), 226 (45), 225 (32), 202 (67), 196 (48), 144 (64), 143 (24), 117 (27), 115 (18), 91 (24), 79 (87). HRMS calculated for C32H33N2O4 [M–NO2]: 511.2597; found 511.2602.
General procedure for the synthesis of pyrrolizines endo-15-18: To a stirred solution of methyl prolinate 11-14 (0.1 mmol) in toluene (1 mL) crotonaldehyde (0.1 mmol, 8.3 µL) and N-phenylmaleimide (0.1 mmol, 17.3 mg) were added. The reaction mixture was stirred overnight at room temperature and the solvent was evaporated under reduced pressure. The crude mixture was purified by flash column chromatography over silica gel (20% EtOAc in hexane as the eluent) to furnish the corresponding product.

Methyl (3aS*,4S*,8aR*,8bR*)-1,3-dioxo-2-phenyl-4-[(E)-prop-1-en-1-yl]octahydropyrrolo[3,4-a]pyrrolizine-8a(6H)-carboxylate (endo-15): The representative procedure was followed by using L-proline methyl ester 11 (0.1 mmol, 12.9 mg). The desired product was obtained as sticky yellow oil (21.6 mg, 61% yield), IR (neat) ν_max: 1707, 1498, 1376, 1215, 1176, 967, 733 cm⁻¹. ¹H NMR δ: 1.78 (dd, J = 6.5, 1.6 Hz, 3H), 1.80-1.98 (m, 1H), 1.99-2.15 (m, 1H), 2.36-2.44 (m, 1H), 2.59-2.72 (m, 2H), 3.18 (ddd, J = 10.4, 8.1, 3.0 Hz, 1H), 3.52 (t, J = 8.4 Hz, 1H), 3.81 (s, 3H), 4.04 (d, J = 8.4 Hz, 1H), 4.13 (t, J = 8.9 Hz, 1H), 5.71 (ddd, J = 15.0, 9.5, 1.6 Hz, 1H), 5.86-6.02 (m, 1H), 7.18-7.34 (m, 2H), 7.35-7.54 (m, 3H). ¹³C NMR δ: 18.1, 24.8, 30.3, 48.9, 51.2, 51.6, 53.3, 65.5, 79.4, 124.2, 126.1, 126.6, 128.8, 129.2, 129.3, 131.8, 133.4, 173.9, 175.5, 176.0. MS (EI) m/z: 354 (M⁺, <1%), 296 (19), 295 (100), 148 (14). HRMS calculated for C₂₀H₂₂N₂O₄: 354.1580; found: 354.1578.

Methyl (3aS,4S,7R,8aR,8bR)-7-hydroxy-1,3-dioxo-2-phenyl-4-[(E)-prop-1-en-1-yl]octahydropyrrolo[3,4-a]pyrrolizine-8a(6H)-carboxylate (endo-16): The representative procedure was followed by using L-4-hydroxyproline methyl ester 12 (0.1 mmol, 14.5 mg). The desired product was obtained as sticky yellow oil (25.6 mg, 69% yield), [α]²⁶_D = -42.4 (c 0.6, CHCl₃), IR (neat) ν_max: 1705, 1377, 1178, 731 cm⁻¹. ¹H NMR δ: 1.79 (dd, J = 6.5, 1.6 Hz, 3H), 2.43 (d, J = 15.4 Hz, 1H), 2.82 (dd, J = 10.4, 4.2 Hz, 1H), 2.96 (dd, J = 15.4, 6.2 Hz, 1H), 3.03-3.32 (br s, 1H), 3.14 (d, J = 10.4 Hz, 1H),
3.61 (t, $J = 8.4$ Hz, 1H), 3.86 (s, 3H), 4.09 (d, $J = 8.4$ Hz, 1H), 4.18 (t, $J = 9.0$ Hz, 1H), 4.40 (t, $J = 5.2$ Hz, 1H), 5.59 (ddd, $J = 15.0$, 9.6, 1.7 Hz, 1H), 5.88-6.02 (m, 1H), 7.17-7.73 (m, 2H), 7.37-7.54 (m, 3H). $^{13}$C NMR $\delta$: 18.2, 40.5, 50.7, 52.1, 53.8, 57.4, 64.7, 72.4, 77.9, 123.5, 126.1, 129.0, 129.4, 131.6, 134.2, 173.5, 175.0, 175.6. MS (EI) $m/z$: 370 (M$^+$, 1%), 312 (21), 311 (100). HRMS calculated for C$_{20}$H$_{22}$N$_2$O$_5$: 370.1529; found: 370.1516.

**Methyl (3aR,3bR,3cR,6aS,7S,9R,9aS)-2-methyl-1,3,4,6-tetraoxo-5,9-diphenyl-7-[(E-prop-1-en-1-yl)dodecahydro-3bH-dipyrrrolo[3,4-a:3',4'-f]pyrrolizine-3b-carboxylate (endo-17):** The representative procedure was followed by using proline ester derivative endo-13 (0.1 mmol, 28.8 mg). The desired product was obtained as colorless prisms (34.3 mg, 67% yield), mp 223-227 °C (Et$_2$O), $[\alpha]_D^{25} = +96.1$ (c 0.9, CHCl$_3$), IR (neat) $\nu_{max}$: 1705, 1436, 1379, 1177, 1060, 963, 733 cm$^{-1}$. $^1$H NMR $\delta$: 1.22 (dd, $J = 6.5$, 1.7 Hz, 3H), 2.77 (s, 3H), 3.41-3.46 (m, 1H), 3.48 (dd, $J = 10.4$, 8.2 Hz, 1H), 3.93 (s, 3H), 4.19-4.26 (m, 1H), 4.30 (d, $J = 8.2$ Hz, 1H), 4.47 (d, $J = 10.4$ Hz, 1H), 4.53 (d, $J = 8.3$ Hz, 1H), 5.16 (ddd, $J = 14.9$, 9.9, 1.7 Hz, 1H), 5.55 (ddd, $J = 14.9$, 6.5, 0.6 Hz, 1H) 7.20-7.25 (m, 4H), 7.30-7.60 (m, 6H). $^{13}$C NMR $\delta$: 17.4, 25.1, 48.6, 50.2, 50.5, 52.5, 53.6, 66.3, 66.9, 81.1, 123.4, 125.8, 127.4, 128.3, 129.3, 129.8, 131.7, 133.8, 138.9, 170.6, 173.7, 174.8, 175.1, 176.1.
